INTEL CORPORATION

INTELLEC 8/MOD 80
MICROCOMPUTER SYSTEM
OPERATOR'S MANUAL

-- TABLE OF CONTENTS --

THE INTELLEC 8I OPERATOR'S MANUAL

LIST OF FIGURES

The INTELLEC 8 can be supplied with either an 8008 or an 8080 CPU chip. This manual uses the term INTELLEC 8I to mean the INTELLEC 8 with 8080 CPU.

This manual assumes that the reader has read and understood the 8080 Programming Manual.

--TERMS AND ABBREVIATIONS--

TERMS:

TERM	DESCRIPTION
Address	A 16 bit number assigned to a memory location corresponding to its sequential position.
Bit	The smallest unit of information which can be represented. (A bit may be in one of two states, 0 or 1).
Byte	A group of 8 contiguous bits occupying a single memory location.
Console	The INTELLEC 8I front panel, containing switches and indicators that allow a user to operate the computer and monitor program execution.
Instruction	The smallest single operation that the computer can be directed to execute.
Object Program	A program which can be loaded directly into the computer's memory and which requires no alteration before execution. An object program is usually on paper tape, and is produced by assembling (or compiling) a source program. Instructions are represented by binary machine code in an object program.
Program	A sequence of instructions which, taken as a group, allow the computer to accomplish a desired task.
Source Program	A program which is readable by a programmer but which must be transformed into object program format before it can be loaded into the computer and executed. Instructions in an assembly language source program are represented by their assembly language mnemonic.

TERMS -- (Continued):

TERM	DESCRIPTION
System Program	A program written to help in the process of creating user programs.
User Program	A program written by the user to make the computer perform any desired task.
Word	A group of 16 contiguous bits occupying two successive memory locations. (2 bytes).

ABBREVIATIONS:

ABBREVIATION	DESCRIPTION
Cr	Carriage return
CPU	Central Processing Unit
Lf	Line feed
PROM	Programmable Read Only Memory
Sp	Space Bar
nnn B	nnn represents a number in binary format.
nnn D	nnn represents a number in decimal format.
nnn O	nnn represents a number in octal format.
nnn Q	nnn represents a number in octal format.
nnn H	nnn represents a number in hexadecimal format.
	Shaded portions of teletype/operator dialog represent teletype output.

1.0 INTRODUCTION

This manual describes how to operate and run programs on the INTELLEC 8I computer. Information provided by this manual can be broadly divided into console operations (Section 3), and use of system software (Sections 4, 5 and 6).

1.1 INTELLEC 8I PURPOSE AND CAPABILITIES

The INTELLEC 8I provides a stand alone computer built around the INTEL 8080 CPU. It has been designed primarily as a system development tool for INTEL 8080 microcomputer users.

Since the entire 8080 CPU is enabled on one LSI chip, certain departures from common computer design are present in the INTELLEC 8I, and to the operator this is most apparent in the INTELLEC 8I console, as described in Section 2.

An input/output system is provided which enables the programmer to use standard devices, such as an ASR-33 teletype, or to supply his own devices for input, output, and listing. In addition, the INTELLEC 8I console has a connector for Programmable Read Only Memories (PROM), thus allowing programs to be loaded directly into PROMs.

Combining the INTELLEC 8I system hardware with system software (summarized in Section 1.2), the user is provided with the capability to generate executable programs, and to load programs into PROMs.

For users who anticipate extensive programming on the INTELLEC 8I, cross assemblers are available, so the programmer may generate object programs on a larger and more powerful computer (any computer having a FORTRAN compiler whose standard integer size is 32 bits or greater), using the INTELLEC 8I for final program checkout and PROM loading only.

1.2 SYSTEM SOFTWARE

INTELLEC 8I system software consists of three programs designed to help a user write, debug and prepare his own programs for execution. The three system programs are:

(1) The MONITOR:
This is the user's principle interface to the INTELLEC 8I. The monitor is pre-loaded on PROMs, and is ready to use as soon as power is applied to the INTELLEC 8 I. It controls the loading and execution of other system and user programs.

(2) The EDITOR:
The editor, used by a programmer to create and correct source program text.

(3) The ASSEMBLER:
The assembler is used to convert source programs into object programs which may be loaded into PROMs or random access memory and executed.

Before operating the INTELLEC 8I computer, a user should throughly understand console operations as described in Sections 2 and 3. Next, execute the system monitor (Section 4), and note the operations that can be executed either via the system monitor, or via the console. Only when console operations and monitor execution are clearly understood should a user execute the editor or assembler.

2.0 HARDWARE ORGANIZATION

In order to understand INTELLEC 8I console operations, it is necessary first to appreciate some aspects of INTELLEC 8I hardware design.

Since the INTELLEC 8I CPU is realized on one LSI chip (INTEL's 8080), external logic cannot interrogate registers or busses that are internal to the LSI chip. Thus, the INTELLEC 8I console does not have any direct access to CPU working registers, the program counter, or the CPU/memory interface; instead the console must access busses external to the CPU in order to perform any operation.

Figure 2-1 provides a very simple illustration of INTELLEC 8I hardware organization as seen by the operator. The console is most accurately visualized as a peripheral device, placed in parallel with the CPU, rather than as an adjunct of the CPU.

Bus (a) carries memory addresses from the console or the CPU to memory, and carries output data from the console or CPU to output ports, and thence to external peripheral devices (e.g., a teletype printer).

Bus (b) carries data from the console or CPU to the memory.

Bus (c) carries data from memory to the console of the CPU.

Bus (d) carries data from input ports to the CPU but not the console. This data is accessable to the console, however, by a process described later.

Bus (e) allows the console to transmit a program interrupt to the CPU.

Bus (f) is a control bus which is used to control instruction execution. Since the console is connected to the control bus, instruction execution can be controlled from the console.

Busses (a), (b), (c), (d) and (f) may be visualized as having three way switches that allow information to be routed to/from the CPU or the console. Since the console is a device designed in parallel to the CPU it contains a considerable amount of parallel logic, including its own data and address registers. Thus, there are certain states in which the CPU remains in control but the console has temporarily suspended operations and there are other states in which the console can completely take over machine operations.

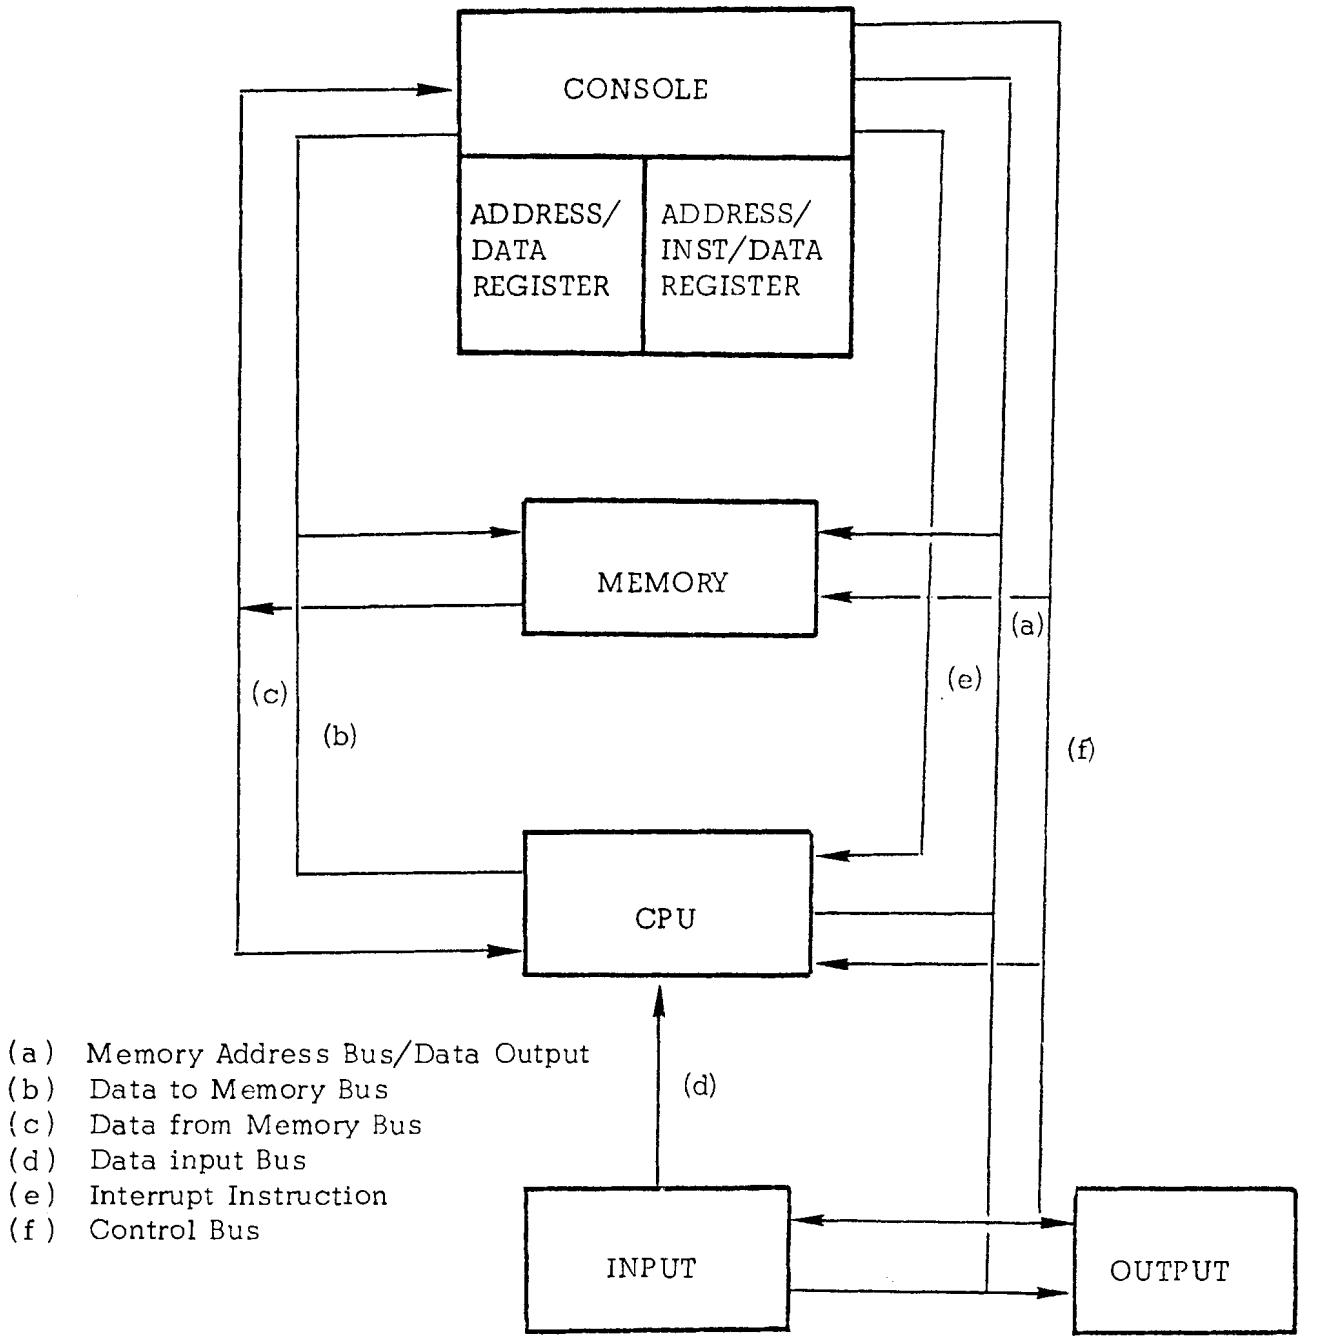

FIGURE 2-1.

A Simplified INTELLEC 8I Block Diagram
Showing the Computer as Seen by the Operator.

Consider now how some operations must be performed, given the hardware organization illustrated in Figure 2-1. Operations are described conceptually below, to provide an introduction to rigorous procedures given later in this manual.

Since the console has its own address and data registers, and since there is a bi-directional bus link between the console and memory, data can be read from memory to console, and written from console to memory directly.

Although there is no direct path for data from input ports to the console, performing an input access operation from the console causes the input data to be sent through the CPU and onto bus (c), where it is displayed on the console.

There is no direct link between the condition bits (carry, sign, zero, parity) and the console.

There is no direct link between CPU registers and the console.

In order to deposit data into a CPU register, it is necessary to deposit the new data into memory, then execute instructions that move the data to the required CPU register.

Sections 4, 5 and 6 provide step-by-step INTELLEC 8I operating instructions, but first the INTELLEC 8I console switches and indicators are described in Section 3.

3.0 OPERATOR'S GUIDE

The INTELLEC 8I is controlled and operated by means of the front panel console and a terminal, which on the standard system is an ASR-33 Teletype. By using these devices, the operator can exercise complete control over the loading, running, and debugging of programs, and can also monitor the status of the INTELLEC 8I as programs run. An optional high-speed paper tape reader allows the operator greater ease in loading programs and data from punched paper tapes.

This section will describe the appearance and operation of the control console, Teletype, and high-speed paper tape reader, and will include information on operating features available to the INTELLEC 8I user.

3.1 CONTROL CONSOLE

Console switches and indicators are used by an operator to control the INTELLEC 8I computer. Indicators provide the status of processor operations, console registers, and memory locations; the switches provide a means of manually loading data into the various console registers, input/output ports, and memory locations. Figure 3-1 is a picture of the INTELLEC 8I front panel. A basic description of the operation and function of each of the switches and indicators is given below.

The summary description of switches and indicators given in Section 3.1.1 and 3.1.2 do not attempt to explain terms or concepts described later in this manual. However, the "SEARCH/WAIT" is one feature of the INTELLEC 8I which must be understood in order to avoid confusion when first reading the switch and indicator descriptions provided below.

The "SEARCH/WAIT" allows the operator to cause program execution to halt upon encountering a memory address which has been passed some fixed number of times in the course of program execution. For a complete description of this feature, see Section 3.2.6.

3.1.1 INDICATORS

All of the indicators on the INTELLEC 8I are Light-Emitting Diodes, or LEDs, and are lit when true.

STATUS INDICATORS

These indicators show the processor status.

1.	RUN	Indicates that the processor is running.
2.	WAIT	Indicates that the processor is waiting for memory or input/output facilities to become available, or that the WAIT switch is set.
3.	HALT	Indicates that the processor is stopped.
4.	HOLD	Indicates that the processor is in the hold state, allowing a memory access or I/O access to be performed by the console. This state may be entered only while the processor is in the WAIT or HALT state.
5.	SRCH COMPL	Indicates that the memory address referred to in a "SEARCH/WAIT" operation has been encountered the required number of times.
6.	ACCESS REQ	Indicates that a console memory access or I/O access operation has been attempted and is waiting to be executed.
7.	INT REQ	Indicates that a console interrupt request has been generated, but has not yet been acknowledged.
8.	INT DISABLE	Indicates that the CPU interrupt system is disabled.

CYCLE INDICATORS

These indicators provide a continuous display of the processor's machine cycle status.

1.	FETCH	Indicates that the processor is performing an instruction fetch from memory.
2.	MEM	Indicates that the processor is performing a memory read or write operation, or that a memory access operation is being performed manually from the control console.
3.	I/O	Indicates that the processor is performing an input/output read/write operation, or that a manual input/output operation is being performed from the control console.
4.	DA	Indicates that a direct access to memory or an I/O port is being performed.
5.	READ/INPUT	Indicates that a memory read or input operation is being performed.
6.	WRITE/OUTPUT	Indicates that a memory write or output operation is being performed.
7.	INT	Indicates that an interrupt operation is in progress.
8.	STACK	Indicates that a stack operation is being performed.

ADDRESS INDICATORS

These indicators display memory and I/O addresses during processor operations.

0-15	These indicators display the memory address being accessed during FETCH, READ, WRITE and manual memory access operations.

0-7	These indicators display the I/O address during a programmed or manual Input/ Output access operation.

INSTRUCTION/DATA INDICATORS

These indicators display the instruction or data passed between the processor and memory, or between the processor and an input/output device.

REGISTER/FLAG DATA INDICATORS

0-7	These indicators display the data byte being written to output port 255 (FFH); thus it is a programmable display.

3.1.2 SWITCHES

The switches on the INTELLEC 8I are considered to be true, or at a logic 1 level, when the top of the switch is pushed in.

ADDRESS/INSTRUCTION/DATA SWITCHES

MEM ADDRESS LOW/INT INST/DATA/PASS COUNT

These switches are used for four functions: to hold the lower eight bits of the memory address during a manual memory access, or "SEARCH/WAIT" operation; to hold the interrupt instruction used with the console interrupt; to hold the data which is to be deposited into memory or an output port; and to hold the pass count during a "SEARCH/WAIT" operation.

ADDRESS/DATA SWITCHES

MEM ADDRESS HIGH/ I/O ADDRESS/SENSE DATA

These switches are used for three functions: to hold the higher 8 bits of a memory address during a manual memory access; to hold an I/O port number during a console I/O access; and to hold SENSE DATA to be used by INPUT instructions when the SENSE switch is set.

ADDRESS CONTROL SWITCHES

These switches control the loading of address or pass count data into the various console registers.

1. LOAD PASS — When depressed, loads the pass count contained in the Address/Instruction/Data switches into the pass count register.

2. DECR — When depressed, decrements the console memory address register by one.

3. INCR — When depressed, increments the console memory address register by one.

4. LOAD — When depressed, loads the address held in the Address switches into the console memory address register for manual memory access operations.

Example: To load the number 3A5F H into the console address register:

Set Address/Data switches 9,11,12, and 13 on, and set Address/Instruction/Data switches 0,1,2,3,4, and 6 on, then press LOAD switch.

Address/Data	Address/Instruction Data
15 14 13 12 11 10 9 8	7 6 5 4 3 2 1 0
0 0 1 1 1 0 1 0	0 1 0 1 1 1 1 1 = 3A5F
	(1 = set, zero = reset)

If the INCR switch is now pressed, the console address register will contain 3A60 H (3A5F+1). This, of course, will not change the settings of the address switches. If the INCR switch is pressed again, the console address register will contain 3A61 H. If the LOAD switch is pressed again, the number 3A5F H held in the address switches is placed again in the console address register.

The state of the console address register during each of these steps is as follows:

	Console Address Register	
Set switches	0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0	
Press LOAD	0,0,1,1,1,0,1,0,0,1,0,1,1,1,1,1	= 3A5F H
Press INCR	0,0,1,1,1,0,1,0,0,1,1,0,0,0,0,0	= 3A60 H
Press INCR	0,0,1,1,1,0,1,0,0,1,1,0,0,0,0,1	= 3A61 H
Press LOAD	0,0,1,1,1,0,1,0,0,1,0,1,1,1,1,1	= 3A5F H

Example: To load a pass count of 11_{10} into the console pass count register (See Section 3.2.6) for a complete description of SEARCH/WAIT - PASS COUNT) :

Set Address/Instruction/Data switches 0,1, and 3 on, then LOAD PASS.

Set switches: Address/Instruction/Data

```
7 6 5 4 3 2 1 0
0 0 0 0 1 0 1 1  =  0B H = 11
                    ( 1 = set,  0  = reset)
```

Pass Count Register unchanged

Press LOAD PASS: Pass Count Register = 00001011

MODE SWITCHES

These switches control the mode of operation of the INTELLEC 8I.

1.	SENSE	When depressed, an input instruction (IN) will take its data from the Address/(SENSE DATA) switches rather than from the input port.
2.	I/O ACCESS	When depressed, provides access to any of the I/O ports if the processor is in the WAIT or HALT state. The accessed port is that whose number appears in Address/Data switches 8-15.
3.	MEM ACCESS	When depressed, provides access to memory.
4.	SRCH-WAIT	When depressed, causes the processor to execute a program up to a certain location, then forces the processor into a WAIT state. (See Section 3.2.6).
5.	WAIT	When depressed, forces the processor into a WAIT state.

CONTROL SWITCHES

These switches provide operator control of the processor.

1. STEP/CONT

   If the processor was forced into the WAIT mode by depressing the WAIT switch, pressing the STEP/CONT switch causes the next instruction to be executed, followed by a return to the WAIT mode.

   After the Search Complete condition forces the processor into the WAIT mode (see Section 3.2.6), pressing the STEP/CONT switch causes normal program execution to continue.

2. DEP

   Deposits the data held in the Address/ Instruction/Data switches into the memory address held in the console address register, or the I/O port whose number is held in Address/Data switches 8-15.

3. DEP AT HLT

   If this switch is set, and the DEP switch is set, and either the MEM ACCESS or I/O ACCESS switch is set, and a program HALT is executed, then the 8 bit data word held in the Address/Instruction/Data switches will be deposited at the memory address held in the console address register or the I/O port whose number is held in Address/Data switches 8-15.

4. INT

   When depressed, this switch causes the processor to execute an interrupt cycle, using the interrupt instruction contained in the Address/Instruction/Data switches.

5. RESET

   When depressed, this switch forces the processor to begin program execution at location zero by executing an RST 0 instruction which is a CALL to location 0. The UART is also reset. (See the INTELLEC 8 Reference Manual).

Example: If the SENSE switch is set, and Address/Data Switches 10,11,13, and 15 are set, then any input instruction will place the number AC H into the accumulator:

```
Address/Data
15 14 13 12 11 10 9 8
 1  0  1  0  1  1 0 0  = AC H
```

Example: If the WAIT and I/O ACCESS switches are set, Address/Instruction/Data switches 1,3, and 4 are set, and Address/Data switches (I/O address) 10, 11, and 13 are set, then pressing the DEP switch will cause the number 1A H to be sent to output port number 2C H:

```
Address/Data                    Address/Instruction/Data
15 14 13 12 11 10 9 8           7 6 5 4 3 2 1 0
 0  0  1  0  1  1 0 0           0 0 0 1 1 0 1 0
    \_____v_____/                   \___v___/
2C H= output port number        1A H = DATA SENT
```

Example: If the WAIT switch is set, the console address register contains 20A1 H, and the Address/Instruction/Data switches are set as in the preceding example, then pressing the DEP switch will cause the number 1A H to be placed at memory location 20A1 H.

Example: If Address/Instruction/Data switches 0,1,2,4,6, and 7 are set, pressing the INT switch will cause the processor to begin an interrupt cycle, executing the instruction RST 2, which is encoded as D7 H.

```
Address/Instruction/Data    (INT INST )
7 6 5 4 3 2 1 0
1 1 0 1 0 1 1 1  = D7 H = RST 2
```

POWER AND PROM PROGRAMMING SWITCHES

1.	PRGM PROM PWR	This switch provides the high voltage used by the PROM programmer.
2.	POWER	This switch is the key-operated main power switch.

PROM SOCKET

This socket is used to hold the 1602A or 1702A PROM (Intel's electronically programmable and ultraviolet erasable memory) to be programmed.

3.2 OPERATING THE INTELLEC 8I

3.2.1 STARTING THE INTELLEC 8I

Before attempting to start the INTELLEC 8I, ensure that the following conditions are met:

(1) The line cord must be inserted firmly into the socket, and the supply voltage must be at the proper level.

(2) All devices attached to the INTELLEC 8I must be turned OFF.

(3) All control and data switches should be switched OFF; (i.e., the bottom of the switch should be in.

(4) The PROM PRGM PWR switch should be off, and no PROM module should be in the PROM socket.

Insert the key into the POWER switch and turn it to the ON position. This applies power to the INTELLEC 8I. The INTELLEC 8I is now in the HALT state and ready for operation.

3.2.2 LOADING DATA INTO MEMORY

Any data which are to be loaded into memory may be loaded in one of two ways: by means of the System Monitor program, discussed in Section 4, or by hand from the console, as described below.

To load data into the INTELLEC 8I via the console follow these steps:

1. Press the MEM ACCESS switch, to enable memory access.

2. Set into the Address switches, the first memory byte address into which data is to be loaded.

3. Press the LOAD switch, to load the memory address into the console address register.

4. Set the data which you wish to load into the ADDRESS/INSTRUCTION/ DATA switches.

5. Press the DEP switch, the data will be loaded into the addressed memory location.

6. If the next byte of data is to be loaded into the next sequential memory location, press the INCR switch once, to increment the memory address by one. If not, return to step 3.

7. Return to step 5.

The most efficient way to manually load large amounts of data into memory is to load it in sequential order, from the lowest memory location to the highest.

Example: Load the instruction JMP 3800 H into memory beginning at location 0. (This instruction will cause a jump to the INTELLEC 8I system monitor). The instruction is encoded as C30038H. The following process is used:

1. Press the MEM ACCESS switch, enabling a memory access.

2. Set the Address/Data and Address/Instruction/Data switches all to 0 (indicating memory location 0).

3. Press the LOAD switch, setting the console address register to 0.

4. Set the Address/Instruction/Data switches to C3 H (set switches 0, 1, 6, and 7).

5. Press the DEP switch. Location 0 now holds C3 H.

6. Press the INCR switch. The console address register now = 1.

7. Set the Address/Instruction/Data switches to 0.

8. Press the DEP switch. Location 1 now holds 00 H.

9. Press the INCR switch. The console address register now = 2.

10. Set the Address/Instruction/Data switches to 38 H (set switches 3, 4, 5).

11. Press the DEP switch. Location 2 now holds 38 H.

The entire instruction is now loaded.

3.2.3 EXAMINING MEMORY

To examine the contents of memory from the control console, perform the following steps:

1. Press the MEM ACCESS switch.

2. Set the address you wish to examine into the address switches.

3. Press the LOAD switch, loading the address into the console address register.

4. The contents of the selected memory location will be displayed in the Instruction/Data indicators.

5. If the next piece of data you wish to see is in the next sequential memory location, press INCR. The data from the next location will be displayed as in step 5. If not, return to step 3.

6. Return to step 3.

Example: Suppose that locations 0 through 2 contain the data C30038H as in the example of section 3.2.2. To verify this, use the following procedure:

1. Press the MEM ACCESS switch.

2. Set the Address/Data and Address/Instruction/Data switches all to 0 (indicating memory location 0).

3. Press the LOAD switch, setting the console address register to 0. Instruction/Data Indicators 0, 1, 6, and 7 will light, indicating that C3 H is the data in location 0.

4. Press the INCR switch. The console address register will now contain 1, and none of the Instruction/Data Indicators will light, indicating that location 1 contains 00 H.

5. Press the INCR switch. 38 H will appear in the Instruction/Data Indicators.

3.2.4 EXECUTING AN INSTRUCTION SUPPLIED BY THE CONSOLE

When the CPU recognizes a console interrupt request, it executes the instruction whose hexadecimal encoding is held in the Address/Instruction/Data switches. This enables the operator to supply the CPU with a one-byte instruction to be executed from the console. The procedure is as follows:

1. Set the WAIT switch.

2. Set the encoding of the instruction to be supplied by the console into the Address/Instruction/Data switches.

3. Press the INT switch.

4. Press the STEP/CONT switch repeatedly, until the INT and FETCH indicators are lit. (This enables the CPU to complete the instruction at which the WAIT occurred, and to fetch the interrupt instruction from the console).

5. Press the STEP switch once. The instruction set into the A/I/D switches has now been executed.

6. Reset the WAIT switch, and program execution resumes with the instruction following the one at which the WAIT occurred.

3.2.5 RUNNING A PROGRAM (USING RESET)

If your program has a starting address of zero, all that is necessary to begin execution is to press the reset switch. The INTELLEC 8I will automatically execute an RST 0 instruction, causing program execution to begin at memory address 0. Otherwise, use the following procedure to place a "jump" to your program's starting address at location 0. Pressing RESET will cause this jump to be executed, transferring control to the program.

1. Press the MEM ACCESS switch.

2. Place all of the Address switches into the 0 position, giving an address of 0000 H.

3. Press the LOAD switch, loading the 0000 H address into the console address register.

4. Place C3 H into the Address/Instruction/Data switches. This is the 8080 operation code for a Jump instruction.

5. Press the DEP switch to load the Jump code into memory location 0000 H.

6. Press the INCR switch one time to increment the memory address.

7. Place the low order eight bits of the starting address of your program into the Instruction/Data switches. The JUMP instruction format requires that the low order byte be given first.

8. Press the DEP switch.

9. Press the INCR switch once.

10. Place the high order eight bits of the starting address into the Address/ Instruction/Data switches.

11. Press the DEP switch.

12. Turn the MEM ACCESS switch to the OFF position.

13. Press the RESET switch. This will cause the INTELLEC 8I to begin execution at location 0000 H, which now contains a Jump instruction to the starting address of your program.

Example: Execute the System Monitor, which resides at location 3800 H.

1. Set the MEM ACCESS switch.

2. Set all the Address switches to 0, indicating memory location 0.

3. Press the LOAD switch.

4. Set the Address/Instruction/Data switches to C3 H.

5. Press the DEP switch.

6. Press the INCR switch.

7. Set the Address/Instruction/Data switches to 00 H.
(The low order byte of the jump address)

8. Press the DEP switch.

9. Press the INCR switch.

10. Set the Address/Instruction/Data switches to 38 H.
(The high order byte of the jump address)

11. Press the DEP switch.

12. Reset the MEM ACCESS switch.

13. Press the RESET switch. The "jump to 3800 H" instruction will be executed, transferring control to the System Monitor.

3.2.6 SEARCH/WAIT AND PASS COUNT

The PASS COUNT feature allows the INTELLEC 8I to count the number of times an operator-specified memory address is encountered and passed during execution of a program, and, when this count reaches a specified number, to enter the WAIT mode upon encountering this address again.

To use this feature, first set the WAIT switch to stop the processor. Then load a pass count (using the binary representation of the count) into the console's pass count register. This is done by setting the Address/Instruction/Data switches to the pass count, and pressing the LOAD PASS switch. Then, set the memory address to be monitored into the Address switches, load this address into the console memory register, set the SEARCH/WAIT switch, reset the WAIT switch, and begin execution of the program. It the pass count were set to N, the CPU would execute the instruction at the indicated address N times, and enter the WAIT state upon encountering the address for the N + 1st time.

Example: Suppose the following program section appears in memory:

MEMORY ADDRESS		INSTRUCTIONS		ASSEMBLED INSTRUCTIONS
0100		MVI H,02		2602
0102		MVI L,00		2E00
0104		MVI M,0	; STORE 0 IN 0200H	3600
0106		XRA A	; SET A=0	AF
0107	BACK:	ADI 1	; ADD 1 to A	C601
0109		MOV M,A	; STORE A IN 0200H	77
010A		JMP BACK		C30701

The first four statements cause memory location 0200 H and the accumulator to be set to 0. The ADI at location 0107 H adds one to the accumulator, and the MOV stores the accumulator at location 0200 H. Control then passes back to location 0107 H, where the accumulator is again incremented.

In order to cause the INTELLEC 8I to execute the ADI 14 times and to enter the WAIT state upon reaching it for the fifteenth time, use the following procedure:

1. Set the WAIT switch.

2. Set Address/Instruction/Data switches 1, 2, and 3 to 1 (representing E H = 14_{10}).

3. Press LOAD PASS, loading 14 into the console pass count register.

4. Set the Address switches to 0107 H, the memory address to be monitored.

5. Press the LOAD switch, setting the console address register to 0107 H.

6. Set the SEARCH/WAIT switch.

7. Reset the WAIT switch and begin execution of the program.

8. The WAIT and SEARCH COMPL indicators will light, indicating that the instruction at 0107 H has been executed and passed 14 times, and the CPU is waiting at this location.

If memory location 0200 H is displayed using the procedure of Section 3.2.3, it will be seen to contain 0E H.

3.3 I/O SYSTEM

The INTELLEC 8I can support a number of input/output devices, from the teletype and high speed paper tape reader to devices supplied by the user. In general, it may be convenient to have two devices which can perform the same function, but to use them for different purposes at various times. For example, if a program is being assembled, you might want the program listing to be written on one device, while any system messages not relevant to the assembly would be written on a separate device.

The I/O system described below permits this type of change. Devices may be assigned functions via a System Monitor command (see Section 4.2.1) or via the user's program. That is, it is possible to write programs which read from several different input devices and write to several different output devices of the program's choosing, without requiring any human intervention.

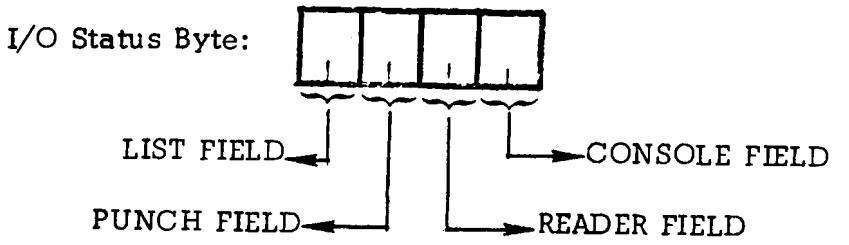
3.3.1 LOGICAL AND PHYSICAL DEVICES

Regardless of how many I/O devices a particular INTELLEC 8I has, there are only four operations which can be performed to any of them. For example, a punch operation can be performed either to the teletype punch or a high speed punch. All system programs and user-written programs, therefore, access four LOGICAL DEVICES (i.e., a PUNCH device) which are then translated to a PHYSICAL DEVICE (i.e., a high speed punch) by the I/O system.

The four logical devices available to programs are:

- CONSOLE — An interactive, character-oriented device used for both input and output.
- READER — A character-oriented, input-only device which transfers data on command and signals the program when there is no more data (an end-of-file condition).
- PUNCH — A character-oriented, output-only device which accepts a character from the program and records it on some external medium.
- LIST — A character-oriented, output-only device which accepts a character from the program and records it on some external medium in human readable form.

Each of these four logical devices may be associated with one of four physical devices at any instant, giving a total of 16 physical devices. The mapping from logical to physical devices is specified by an I/O status byte which resides in memory and is accessible to system and user programs via I/O subroutines described in the next section. The possible mappings appear as follows:



LOGICAL DEVICES	IOCHK FIELD	PHYSICAL DEVICES
	00	TTY
CONSOLE ——→	01	CRT
	10	BATCH (READER=CONSOLE INPUT LIST=CONSOLE OUTPUT)
	11	1 (user console device)
	00	TTY
READER ——→	01	PTR
	10	1 (user reader device 1)
	11	2 (user reader device 2)
	00	TTY
PUNCH ——→	01	PTP
	10	1 (user punch device 1)
	11	2 (user punch device 2)
	00	TTY
LIST ——→	01	CRT
	10	1 (user list device 1)
	11	2 (user list device 2)

At cold start or system reset, the I/O status byte is set equal to 00H, causing the teletype to be selected for all logical devices.

3.3.2 I/O SUBROUTINES

The way in which a program performs an I/O operation to any of the four logical devices is by calling the appropriate subroutine supplied by the I/O system. The available subroutines and their locations in memory are given in the following table:

ROUTINE	FUNCTION	MEMORY LOCATION
CI	Console input	3803H
RI	Reader input	3806H
CO	Console output	3809H
PO	Punch output	380CH
LO	List output	380FH
CSTS	Console input status	3812H
IOCHK	Check I/O mapping	3815H
IOSET	Set I/O mapping	3818H
MEMCK	Check size of memory	381BH

The rest of this section gives a description and examples of how to call these subroutines.

CI - CONSOLE INPUT

This routine returns a character received from the selected console device to the caller in the A register. The A register and the condition bits are affected by this operation.

Example:

```
          Assembly Language

CI        EQU     3803H
          ...
          CALL    CI
          STA     DATA
          ...
```

PL/M

```
CI:
     PROCEDURE BYTE;
          DECLARE IOCI LITERALLY '3803H';
               GO TO IOCI;
     END CI;
               ...
     DATA = CI;
               ...
```

CO - CONSOLE OUTPUT

CO transmits a character, passed from the calling program in the C register, to the device selected for console output. The A and C registers and the condition bits are affected.

Example:

```
          Assembly Language

CO        EQU     3809H
          ...
          MVI     C,'.'
          CALL    CO              ; PRINT '.' ON CONSOLE
          ...
                PL/M

CO:
     PROCEDURE (CHAR);
          DECLARE CHAR BYTE;
          DECLARE IOCO LITERALLY '3809H';
               GO TO IOCO;
          END CO;

     CALL CO('.');
```

RI - READER INPUT

RI returns a character read from the reader device in the A register. If no character was read from the device (i.e., end of file), the CARRY condition bit is set equal to 1, and the A register is zeroed. If data is ready, the CARRY bit is zeroed. If no character is received from the physical device within a pre-established time, an end of file is simulated and control is returned to the calling program.

Example:

Assembly Language

```
RI          EQU     3806H
            ...
            CALL    RI
            JC      EOF       ; END OF FILE SENSED
            STA     DATA
            ...
```

PL/M

```
RI:
    PROCEDURE BYTE;
        DECLARE IORI LITERALLY '3806H';
            GO TO IORI;
        END RI;
            ...
    DATA = RI;
    IF CARRY THEN GO TO EOF$LOC;
```

PO - PUNCH OUTPUT

PO transmits a character from the calling program to the device selected as the punch device. PO is identical in format to CO, the only difference being the entry point address, '380CH'.

LO - LIST OUTPUT

LO performs the same function to the selected list device as CO and PO do to their selected devices. It's entry point address is '380FH'.

CSTS - CONSOLE INPUT STATUS

In many applications, there is a need to 'poll' the console device to see if the operator wishes to interrupt the current task and do something else. The CSTS routine allows the caller to test the console to see if a character is ready for input. CSTS returns a logical value in the A register (true = 0FFH, false = 0) indicating whether or not a key has been depressed. The user may then use CI to read the character.

Example:

Assembly Language

```
CSTS        EQU     3812H
            ...
            CALL    CSTS
            RRC
            JNC     CONTINUE        ; NO CHARACTER
            CALL    CI
            CPI     BREAK
            JZ      BREAKIT         ; INTERRUPT PROCESSING
CONTINUE:
            ...
```

PL/M

```
CSTS:
    PROCEDURE BYTE;
        DECLARE IOCS LITERALLY '3812H';
            GO TO IOCS;
        END CSTS;
            ...
        DO WHILE NOT CSTS;
            ...
        END;
        IF CI<>BREAK THEN
        DO;
            ...
        END;
```

IOCHK - CHECK I/O SYSTEM CONFIGURATION

IOCHK returns an 8-bit value in the A register which describes the current assignment of physical devices to logical devices. The calling program can test selected bits in the byte returned and determine the current status of the system. For a detailed description of this I/O status byte, see section 3.3.1.

Example:

Assembly Language

```
IOCHK       EQU     3815H
            ...
            CALL    IOCHK
            ANI     CMSK    ; MASK ALL BUT CONSOLE
            SUI     CCRT    ; IS IT A CRT?
            JZ      CRTO    ; YES
```

PL/M

```
IOCHK:
      PROCEDURE BYTE;
          DECLARE IOCHECK LITERALLY '3815H';
               GO TO IOCHECK;
          END IOCHK;
                ...
      IF (IOCHK AND CMSK) = CCRT THEN
      DO;
                ...
      END;
```

IOSET - SET I/O SYSTEM CONFIGURATION

IOSET allows the user to modify the I/O status byte, thus changing the assignment of physical devices to logical devices.

Example:

Assembly Language

```
IOSET       EQU     3818H
            ...
            CALL    IOCHK           ; GET STATUS
            ANI     NOT CMSK        ; CLEAR CONSOLE BITS
            ORI     CTTY            ; CONSOLE = TTY
            MOV     C,A
            CALL    IOSET           ; STORE MODIFIED I/O BYTE
```

PL/M

```
IOSET:
      PROCEDURE (CHAR);
          DECLARE IOS LITERALLY '3818H';
          DECLARE CHAR BYTE;
               GO TO IOS;
          END IOSET;
                ...
      CALL IOSET ((IOCHK AND NOT CMSK) OR CTTY);
```

MEMCK - DETERMINE SIZE OF RAM MEMORY

This subroutine gives the user the ability to determine the highest RAM address currently available in the system. The MEMCK routine is equivalent to a PL/M address function and the 16 bit value it returns in the A and B registers is the highest address available to the user after the system monitor has allocated its own storage at the top of memory.

Example:

Assembly Language

```
MEMCK       EQU     381BH
            ...
            CALL    MEMCK
            LXI     H,MAXMEM
            MOV     M,A             ; LOW-ORDER BYTE IN A
            INX     H
            MOV     M,B             ; HIGH-ORDER BYTE IN B
```

PL/M

```
MEMCK:
    PROCEDURE ADDRESS;
        DECLARE MEMSIZ LITERALLY '381BH';
            GO TO MEMSIZ;
        END MEMCK;
            ...
    DECLARE MAXMEM ADDRESS;
            ...
    MAXMEM = MEMCK;
```

3.3.3 USER-SUPPLIED DEVICES

This section describes the necessary steps in hooking up a user-supplied I/O device to the I/O system.

The I/O subroutines described in Section 3.3.2 assume that programs (called drivers) exist which perform the actual transfer of data between I/O devices and the CPU. For instance, when the console input routine is called, it checks to see which physical device is assigned to the console, and then branches to the driver appropriate to the device. (Examples of drivers for the teletype are given in Appendix G). Therefore, when the user supplies his own device, he must:

1) Write a program to perform the data transfer, making sure that the program saves and restores any CPU registers it uses that are not specifically changed by the I/O subroutine.

2) Store a JMP to this driver's address in the appropriate location as defined in the following table:

MEMORY LOCATION	USE
3700H	USER DEFINED CONSOLE INPUT
3703H	USER DEFINED CONSOLE OUTPUT
3706H	USER DEFINED READER (1)
3709H	USER DEFINED READER (2)
370CH	USER DEFINED PUNCH (1)
370FH	USER DEFINED PUNCH (2)
3712H	USER DEFINED LIST (1)
3715H	USER DEFINED LIST (2)
3718H	USER DEFINED CONSOLE STATUS

Thus, if the user supplied a custom built listing device, he would write a driver to transfer data to it in an appropriate manner, then store the JMP to the driver's address at location 3712H. By assigning LIST=1, his device would receive any listing output generated.

3.4 ASR-33 TELETYPE DESCRIPTION

The basic input-output device for the INTELLEC 8I is the ASR-33 Teletype, which consists of a printer, keyboard, paper tape reader and paper tape punch.

The ASR-33 Teletype is pictured in Figure 3-2 and has its major controls labeled. The function of each of the controls is listed below:

CONTROL KNOB	3-position knob. OFF: turns off Teletype console. LINE: Teletype is on and attached to INTELLEC 8I as an Input-Output device. LOCAL: Teletype is on but not attached to INTELLEC 8I.
KEYBOARD	The keyboard is illustrated in Figure 3-2 and is similar to a typewriter keyboard. Several non-printing control characters are included and can be used by depressing the CONTROL key and then depressing the selected character key.
PRINTER	The printer produces a typed copy of input and output at a maximum rate of ten characters per second. When the control knob is in the LINE position, the printer types outputs transmitted from the computer. When the control knob is in the LOCAL position, the printer prints in response to keyboard operation.
TAPE PUNCH	The tape punch is used to record information on punched paper tape at a rate of 10 characters per second.
REL	Disengages the paper tape to allow loading or unloading of tape.

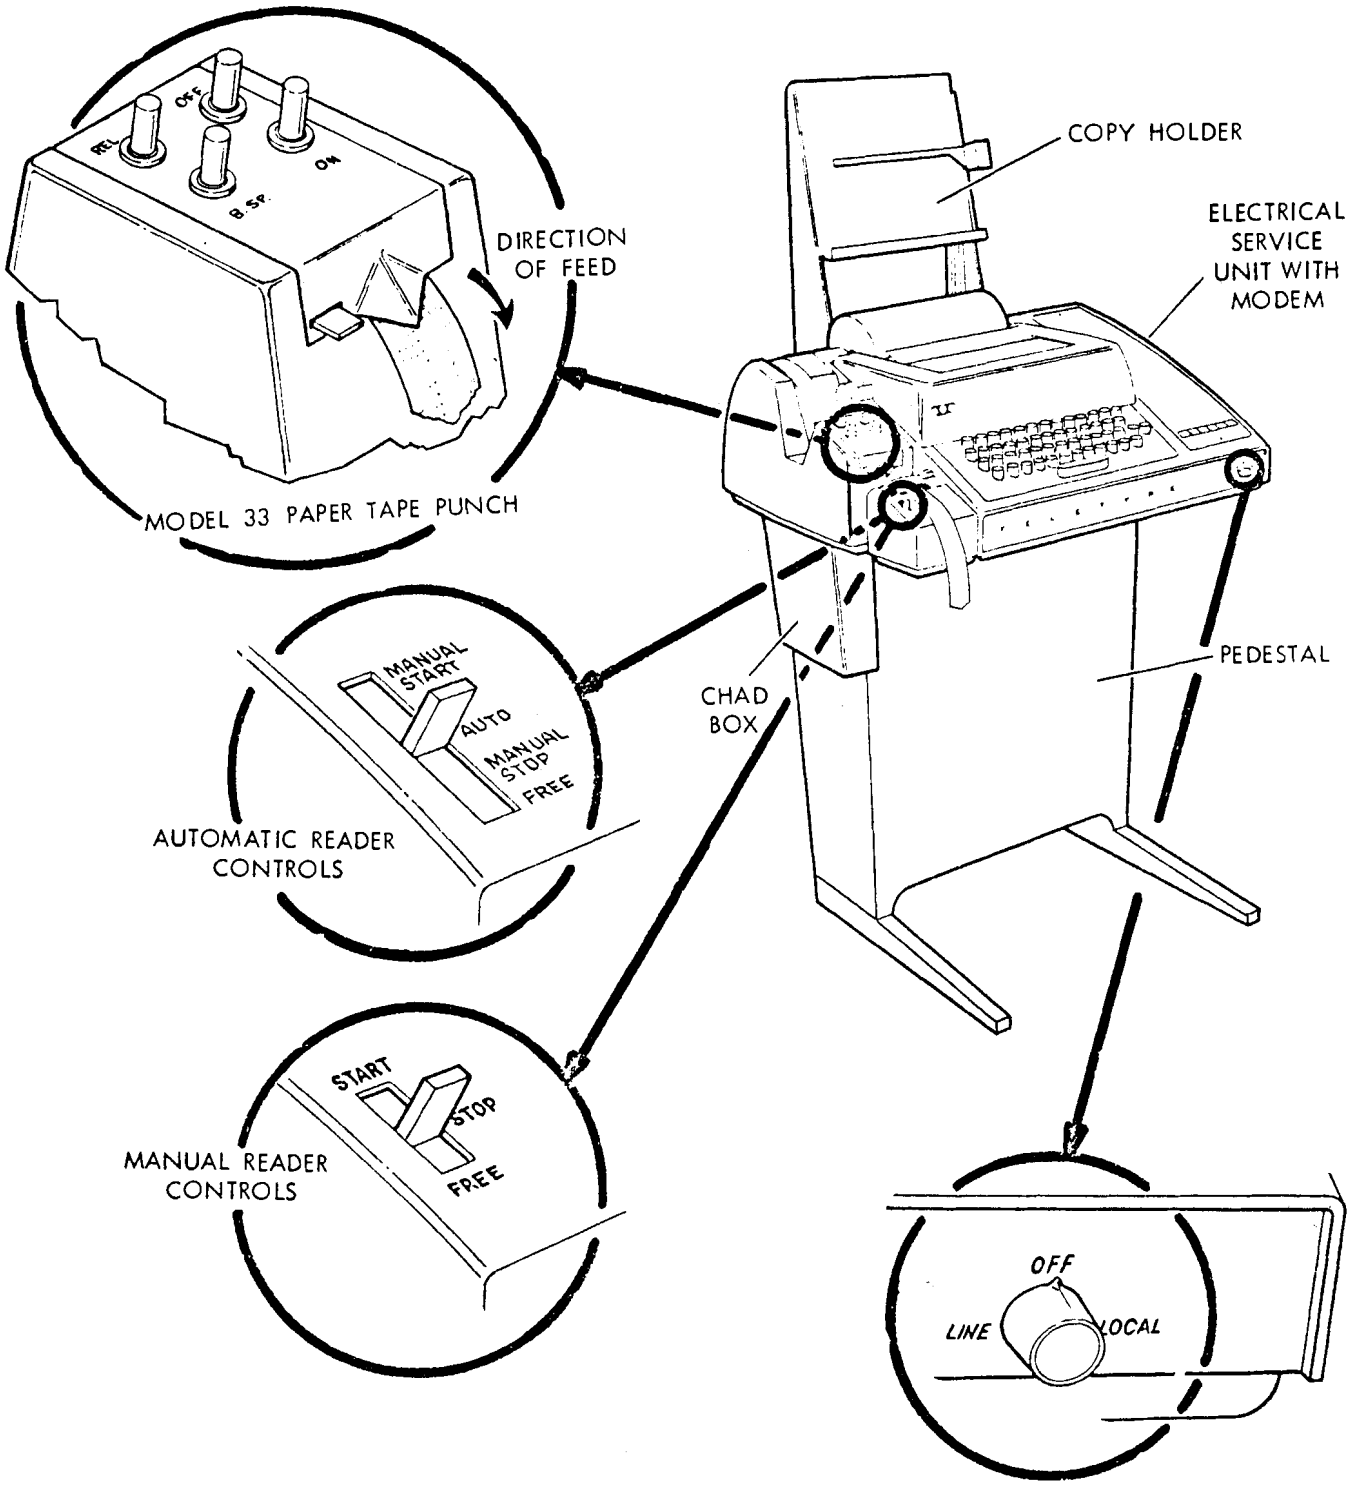


FIGURE 3-2.

ASR-33 Teletype Keyboard and Controls.

B.SP.	Backspaces the paper tape one character for each depression.
ON	Engages the tape punch and enables punching of tape.
OFF	Disengages the tape punch.
TAPE READER	The tape reader reads information punched on paper tape at a ten character per second rate.
START	Begins tape reading.
STOP	Stops tape reading.
FREE	Disengages paper tape in the reader and allows tape to be pulled through reader.

3.5 TELETYPE OPERATION

Operation of the ASR-33 Teletype is a simple task. There are few operational controls that are not self-explanatory, and so operation can be learned in an extremely short time. The more sophisticated operations are described in this section.

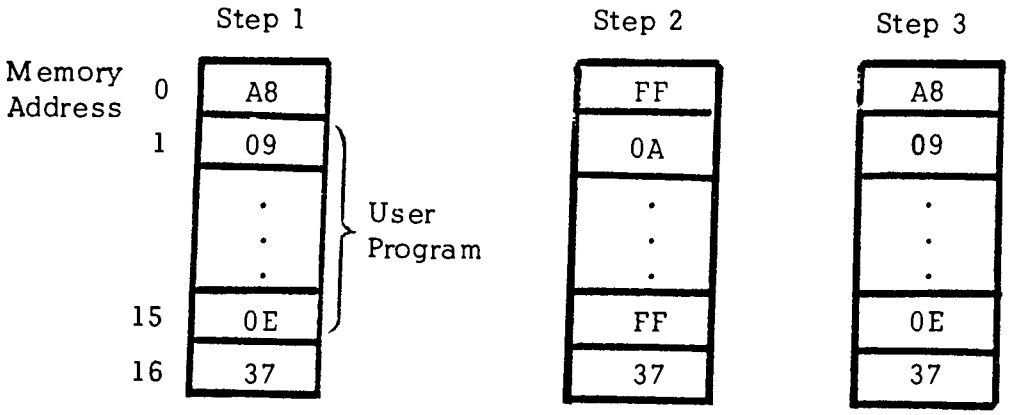
3.5.1 LOADING THE TAPE READER

To load the tape reader, first lift the plastic cover over the sprocket wheel. Place the control switch into the FREE position, and then place your tape onto the tape reader, with the sprocket holes to your left. Close the tape reader cover, ensuring that the tape is still in place.

4.0 SYSTEM MONITOR

The INTELLEC 8I System Monitor enables the operator to easily manipulate the contents of memory, read and produce paper tapes, execute programs, and read or initialize PROMs.

The System Monitor, and all INTELLEC 8I system software in general, use the first 16 memory locations for storage of temporary data. Therefore if the operator runs a program beginning in these locations, and then uses the System Monitor, Text Editor, or Assembler, he must re-load the first 16 bytes of his program before running it again. Alternatively, programs could be written beginning at location 16. Then system programs and user programs could be executed in any order, without requiring the re-load operation.



Step 1 shows the first 17 bytes of memory while a user program beginning at location 0 is being run.

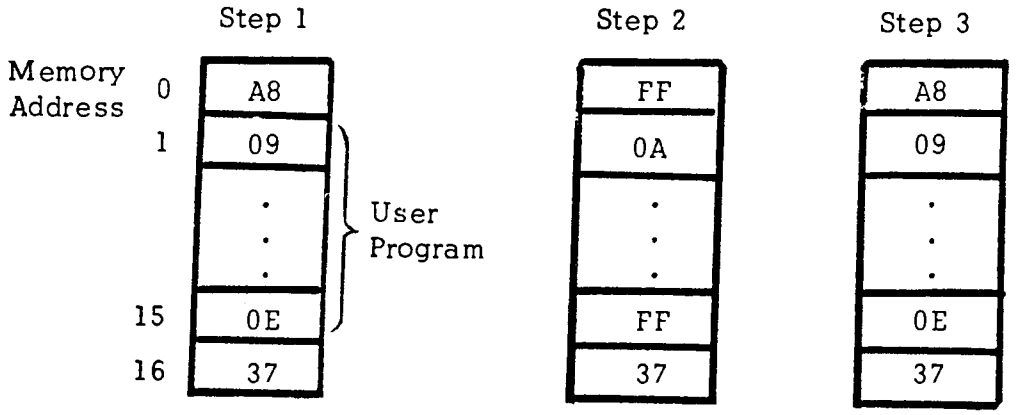
Step 2 shows these bytes after the System Monitor has been run, changing the first 16 bytes of memory (0-15). Bytes 16 on are unchanged.

Step 3 shows that the user has reloaded the first 16 bytes of his program, and is ready to execute the program again.

4.0 SYSTEM MONITOR

The INTELLEC 8I System Monitor enables the operator to easily manipulate the contents of memory, read and produce paper tapes, execute programs, and read or initialize PROMs.

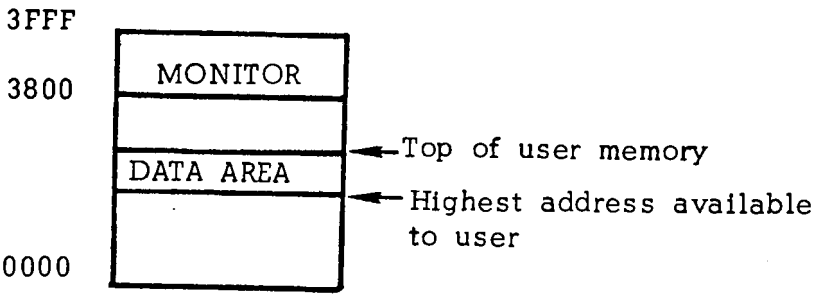
The System Monitor, and all INTELLEC 8I system software in general, use the first 16 memory locations for storage of temporary data. Therefore if the operator runs a program beginning in these locations, and then uses the System Monitor, Text Editor, or Assembler, he must re-load the first 16 bytes of his program before running it again. Alternatively, programs could be written beginning at location 16. Then system programs and user programs could be executed in any order, without requiring the re-load operation.



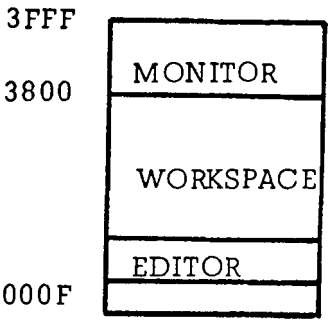
Step 1 shows the first 17 bytes of memory while a user program beginning at location 0 is being run.

Step 2 shows these bytes after the System Monitor has been run, changing the first 16 bytes of memory (0-15). Bytes 16 on are unchanged.

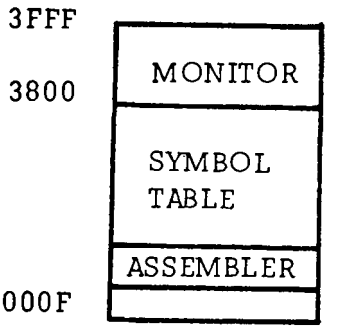
Step 3 shows that the user has reloaded the first 16 bytes of his program, and is ready to execute the program again.



a) Initial power-on



b) Load editor and generate source code in workspace.



c) Load assembler and convert source code to object code.

Figure 4-1: Normal Use and Execution Sequence for System Software

The System Monitor is the operator's interface to INTELLEC 8I, and controls loading and execution of the editor and assembler, loading and execution of user programs, and to some extent the debugging of user programs. Figure 4-1 illustrates memory utilization during various stages of system software use. While the System Monitor is running, it uses an area at the top of memory for data storage and scratch work. The user can determine how large this area is via the I/O subroutine MEMCK (described in section 3.3.2), which returns the highest memory address available for the user.

4.1 SYSTEM MONITOR IMPLEMENTATION AND EXECUTION

4.1.1 SYSTEM MONITOR IMPLEMENTATION

The INTELLEC 8I System Monitor program is implemented on eight PROM modules, which are pre-installed into each INTELLEC 8I. This allows System Monitor to be used with great ease, as it is not necessary to wait for lengthy paper-tape loading operations. All that is required to go on-line with System Monitor is to start the INTELLEC 8I, turn the Teletype on-line, perform a program jump to the execution address of System Monitor (3800), and begin execution.

4.1.2 STARTING SYSTEM MONITOR

To begin operating System Monitor, place a "Jump to 3800" command (C30038 H) into the first three locations in the INTELLEC 8I. Press the RESET button and the INTELLEC 8I will automatically jump to the starting address of System Monitor, 3800. (For the exact sequence, see Section 3.2.2).

4.2 SYSTEM MONITOR OPERATION AND COMMANDS

A monitor command consists of a single letter typed into the Teletype keyboard followed by a number of arguments, possibly none. The arguments are separated, if there are more than one, by spaces or commas. A command is terminated and executed by typing a carriage return or space, depending upon the command.

4.2.1 A COMMAND (ASSIGN I/O DEVICES)

The format of the A command is:

A ldev = pdev

ldev is one of the four logical I/O devices CONSOLE, READER, PUNCH or LIST. Only the first character is required, the rest being optional.

pdev is one of the four legal physical I/O devices corresponding to ldev, as shown in Table 4-1.

Description: The physical device pdev is assigned to logical device ldev. The following table gives all possible A commands, with optional characters shown in lower case. Numeric values for pdev indicate user-supplied devices.

AConsole = Tty
AConsole = Crt
AConsole = Batch
AConsole = 1
AReader = Tty
AReader = Ptr
AReader = 1
AReader = 2
APunch = Tty
APunch = Ptp
APunch = 1
APunch = 2
AList = Tty
AList = Crt
AList = 1
AList = 2

Table 4-1: I/O Assignment Commands

For a description of the I/O system, see Section 3.3.

Error Conditions:

If a selected physical device has not been readied or does not exist, the monitor's execution will be undefined, usually executing an infinite loop. This may be corrected by readying the device or pressing system reset.

4.2.2 B COMMAND (BNPF OUTPUT)

The format of the B command is:

B low address , high address

Low address is a valid 16-bit memory address.

High address is a valid 16-bit memory address equal to or greater than low address.

Description: The B command outputs the content of memory, from (low address) through (high address), to the Teletype printer/punch in BNPF form. Six inches of null tape are punched before and after the data.

BNPF form represents the data word in pure binary form. A B is punched to indicate the beginning of a word, P is punched to indicate a "1" bit, N is punched to indicate a "0" bit, and F is to indicate the end of a word. Thus, 'A5'H would be shown as follows:

BPNPNNPNPF

Beginning 10100101 End

For reference, the address is punched in decimal form every fourth byte. The reason the addresses are punched in decimal rather than in hexadecimal is to avoid confusion between the character 'B' punched on the tape to indicate the beginning of a byte, and the character 'B' which would have to be punched as part of some hexadecimal addresses. (See Section 4.2.7 for the legal BNPF program tape format.)

Example: If memory bytes 1 through 4 contain 2B 00 FF 55 then the command:

.B1,4(Cr)

typed into the teletype will cause the following to be punched and printed at the teletype:

```
1    BNNPNPNPPF    BNNNNNNNNF    BNPPPPPPPF
4    BNPNPNPNPF
```

Error conditions:

1. If low address or high address is greater than 16 bits, only the last 4 hex digits of the argument will be used as the address.

Example: The command:

.B3C03B00,3CA3C01 (Cr)

is equivalent to the command:

.B3B00,3C01 (Cr)

2. If low address is greater than high address, only the one byte at low address will be punched.

Example: The command:

.B4A00,3A02 (Cr)

is equivalent to the command:

.B4A00,4A00 (Cr)

3. Non-existent memory is equivalent to a string of bytes all containing FF H.

Example: If memory addresses 2000 H- 2003 H are not present in a particular INTELLEC 8I system, then the command:

.B2000,2003 (Cr)

will cause the following to be printed and punched at the teletype:

```
8192    BPPPPPPPPF    BPPPPPPPPF    BPPPPPPPPF
8195    BPPPPPPPPF
```

4. If low address or high address contains an invalid character, or if high address is omitted, the monitor will immediately type '*(Cr)(lf).' and await the next command.

Example: If the user tries to enter the number 3AGE as low address, the following will be printed:

4.2.3 C COMMAND (COMPARE PROM WITH MEMORY)

The format of the C command is:

C address

Address is a valid 16 bit memory address.

Description: The C command causes the monitor to read a PROM plugged into the console programming socket and compare its contents with a 256 byte area of memory starting at address. If the contents of the PROM and memory match completely, no message is given. Otherwise, for each location where a mismatch occurs, the memory address, memory data, and PROM data are printed.

Example: If the command

.C600(Cr)

produces the printout

0600	A3	FF
0605	6D	05

then the PROM contains the same data as memory locations 0600 H through 06FF H, except at location 0600 H and 0605 H. Memory contains A3 H and 6D H, while the PROM contains FF H and 05 H, respectively.

Error Conditions:

1. If address is greater than 16 bits, only the last 4 hex digits are used as the address.

Example: The command:

.C0ABC059(Cr)

is equivalent to the command:

.CC059(Cr)

2. If address specifies a non-existent memory range, the PROM contents are compared to 256 bytes of FF H.

Example: If locations 2000 H through 20FF H are non-existent, and the command

.C2000(Cr)

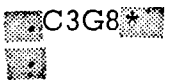
is issued, every PROM byte not equal to FF H will be printed.

3. If a PROM is not installed in the socket, memory contents are compared to 256 bytes of FF H.

Example: If a PROM is not plugged into the socket, any C command will print every byte in the memory range not equal to FF H.

4. If an invalid character is specified in address, the monitor will type '*(Cr)(lf).' and await the next command.

Example: If the user attempts to enter 3GAB as the address, the following will be printed:



4.2.4 D COMMAND (DISPLAY DATA)

The format of the D command is:

D low address , high address

Low address is a valid 16 bit memory address.

High address is a valid 16 bit memory address equal to or greater than low address.

Description: Upon execution of this command, memory data from (low address) to (high address) is displayed upon the list device (normally the Teletype). Data are displayed in hexadecimal form. Up to sixteen bytes per line are printed, preceded by the hexadecimal address of the first byte of that line. A carriage return is forced after a byte having a low order digit of F in its memory address is printed.

Example: Enter at the teletype the command:

.D10F,123(Cr)

and the teletype will type back:

```
010F   AA
0110   BB CC DD EE FF 11 22 33 44 55 66 77 88 99 AB CD
0120   EF 12 34 56
```

where memory locations 010F through 0123 are assumed to contain

AA BB CC DD EE FF 11 22 33 44 55 66 77 88 99 AB CD EF 12 34 56

The D command should be used only to examine memory contents. To punch the memory contents onto a paper tape, either the B command or the W command should be used. These commands produce a punched paper tape in the proper formats, while the D command causes only a simple sequence of characters to be output.

Error conditions:

1. If low address or high address is greater than 16 bits, only the last 4 hex digits of the argument will be used as the address.

Example: The command

.D30010,AB0013(Cr)

is equivalent to the command

.D0010,0013(Cr)

2. If low address is greater than high address, only the one byte at low address will be displayed.

Example: The command:

.D10,6

is equivalent to the command

.D10,10

3. Non-existent memory is equivalent to a string of bytes all containing FF H.

Example: If memory address 2000 H- 2010 H are invalid, then the command:

```
.D2000,2010
```

will cause the teletype to print:

```
2000   FF FF FF FF FF FF FF FF FF FF FF FF FF FF FF FF
2010   FF
```

4. If low address or high address contains an invalid character, or if high address is omitted, the monitor will immediately type '*(Cr)(lf). and await the next command.

Example: If the user attempts to enter the number 0G as an address, the following will be printed:

4.2.5 F COMMAND (FILL MEMORY WITH CONSTANT)

The format of the F command is:

F low address , high address , data

Low address is a valid 16 bit memory address.

High address is a valid 16 bit memory address equal to or greater than low address.

Data is an 8 bit data value.

Description: Execution of this command causes memory locations (low address) through (high address) to be filled with the constant (data).

Example: The command:

.F7,14,AA(Cr)

will set bytes 0007 through 0014 equal to AA H.

```
0007    AA AA AA AA AA AA AA AA AA
0010    AA AA AA AA AA
```

Error Conditions:

1. If low address or high address is greater than 16 bits (or data is greater than 8 bits), only the last 4 (or 2) hex digits will be used.

Example: The command:

.F7AB0007,0014,FFACAA(Cr)

is equivalent to the command:

.F0007,0014,AA(Cr)

2. If low address is greater than high address, data will replace only the byte at low address.

Example: If locations 7,8, and 9 contain AA H, BB H, and CC H, execution of the command:

.F7,1,33(Cr)

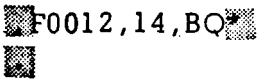
will cause memory to appear as follows:

0007 33 BB CC

3. If a non-existent memory address is specified, this command has no effect.

4. If low address, high address, or data contain an invalid character, the monitor will immediately type '*(Cr)(lf).' and await the next command.

Example: If the user tries to enter BQ as data, the following will be printed:



4.2.6 G COMMAND (GO TO)

The format of the G command is:

G address, bkptl, bkpt2

Address,bkptl, and bkpt2 are valid 16 bit hexadecimal memory addresses.

Description: The G command causes program control to be transferred to location address. If either bkptl or bkpt2 is specified, a breakpoint will be set in the program at the corresponding address(es). The specified address must correspond to the first byte of a program instruction. If either breakpoint is encountered during program execution, the System Monitor will save all program status (CPU registers and condition bits), clear all existing breakpoints, and take control. The user may then examine and/or modify registers or memory, or use any other monitor commands. This feature allows the user to debug portions of a program.

If address is not specified, the program status is restored and the saved value of the program counter is used as the new starting address.

NOTE: Encountering a breakpoint may be simulated at any time by setting the console Address/Instruction/Data switches to CFH and pressing the INT switch. All breakpoints will be cleared, status will be saved, and the System Monitor will take control.

Example: The command:

G24A

will cause program execution to begin at location 24AH, with no breakpoints being set.

The command:

G,12C

will cause a breakpoint to be set at 12CH, and program execution to resume at the address indicated by the saved value of the program counter.

The command:

G

will cause program execution to resume at the address indicated by the saved value of the program counter, with all status restored and no breakpoints set.

Error Conditions:

1. If address is greater than 16 bits, only the last 4 hex digits of the argument will be used as the address.

Example: The command:

.G3C0010(Cr)

is equivalent to the command

.G0010(Cr)

2. If address is a non-existent memory address, the system will attempt to transfer control and then stop with no response. The System Monitor must then be manually restarted.

4.2.7 H COMMAND (HEXADECIMAL ARITHMETIC)

The format of the H command is:

.H number , number Sp

Number is a 16 bit hexadecimal number.

Description: The H command is designed to aid the user in performing hexadecimal arithmetic while using the System Monitor. It causes the sum and difference its arguments to be printed in two's complement hexadecimal form. This command is terminated by a space, rather than by a carriage return.

Example:

.H1E,5C 007A FFC2

Error Conditions:

1. If either number is greater than 16 bits, only the last 4 hex digits are used.

Example: The command:

.H00ABC,23Sp

is equivalent to the command:

.H0ABC,23Sp

2. If number contains an invalid character, the monitor will immediately type '*(Cr)(lf).' and await the next command.

Example: If the user attempts to enter 01P, the following will be printed:

.H01P*

4.2.8 L COMMAND (LOAD BNPF TAPE)

The format of the L command is:

L low address , high address

Low address is a valid 16 bit memory address.

High address is a valid 16 bit memory address greater than or equal to low address.

Description: The L command loads a paper tape punched in BNPF format into memory starting at low address and continuing through high address. BNPF format represents a word in pure binary form. A B is punched to indicate the beginning of a word. Following the B, exactly eight P's and N's must be punched, P indicating a "1" bit and N indicating a "0" bit. The ninth character following the B must be an F, indicating the end of the word. All characters following the F are ignored until another B is encountered. This allows comments (not including the letter B) to appear between data words in BNPF format. For instance, the two hexadecimal data words 3AF0 could be represented on a BNPF tape as follows:

BNNPPPNPNF * COMMENT * BPPPPNNNNF

Example:

.L0,FF(Cr)

When executed, this would load the first page (256 bytes) from paper tape into memory.

Error Conditions:

1. If low address or high address is greater than 16 bits, only the last 4 hex digits of the argument will be used as the address.

Example: The command:

.L0,AF00FF(Cr)

is equivalent to the command:

.L0,00FF(Cr)

2. If low address is greater than high address, only one byte will be read from the paper tape and transferred into memory at low address.

Example: The command:

.L10,0(Cr)

is equivalent to the command:

.L,0,0(Cr)

3. If non-existent memory is referenced, the tape will be read, but no other action will occur.

4. If low address or high address contains an invalid character, the monitor will immediately type '*(Cr)(lf).' and await the next command.

Example: If the user attempts to enter 3GAB as high address, the following will be printed:

.L0,3G*
.

4.2.9 M COMMAND (MOVE MEMORY)

The format of the M command is:

.M low address , high address , destination address

Low address is a valid 16 bit memory address.

High address is a valid 16 bit memory address equal to or greater than low address.

Destination address is a valid 16 bit memory address.

Description: The M command causes the block of memory from low address through high address to be moved to the locations in memory beginning at destination address.

Example: If memory appears as follows:

LOCATIONS		DATA
0300-0304	contain	01020304
0200-0204	contain	A1A2A3A4

then the command:

M200,204,300

will cause the following:

LOCATIONS		DATA
0300-0304	contain	A1A2A3A4
0200-0204	contain	A1A2A3A4

Note: The movement is performed byte by byte: the byte at low address is moved to destination address, then low address+1 is moved to destination address+1, etc. Therefore, the MOVE command may be used to fill memory with a byte or sequence of bytes.

Example: If location 0300 H contains FF H, the command

.M300,310,301(Cr)

will cause locations 300 through 310 to contain FF H. The FF at 300 is moved to 301, then the byte at 301 (which is now FF), is moved to 302, and so on.

Error Conditions:

1. If any address is greater than 16 bits, only the last 4 hex digits are used as the address.

Example: The command:

.M00302,303,00405(Cr)

is equivalent to the command:

.M302,303,405(Cr)

2. If low address is greater than high address, only one byte will be moved from low address to destination address.

Example: The command:

.M300,2F0,100(Cr)

is equivalent to the command:

.M300,300,100(Cr)

3. If low address through high address specifies a non-existent range of memory, bytes of FF H will be moved to the memory locations specified by destination address.

Example: If locations 2000 H through 2005 are non-existent, the command:

.M2000,2005,100(Cr)

will cause locations 0100 H through 0105 H to contain FF H.

4. If an invalid character is entered in an address, the monitor will type '*(Cr)(lf).' and await the next command.

Example: If the user attempts to enter 0BAG as the destination address, the following will be printed:

.M100,10F,0BAG
*

4.2.10 R COMMAND (READ HEX FILE)

The format of the R command is:

R bias address

Bias Address is a 16 bit two's complement hexadecimal number.

Description: This command loads paper tape punched in hexadecimal format (using the W command) into memory. The address at which the tape is loaded is determined by adding the address punched on the tape to the bias address using two's complement arithmetic. The bias may be negative, but in this case must be in two's complement form. If the tape was produced using an E command with a non-zero entry point address (see section 4.2.13), control will be transferred to that location in memory. Otherwise, the System Monitor will remain in control and request another command.

Example: If a tape was punched which began at location 0100 H, the following command:

.RFFB0(Cr)

will cause the tape to be read and loaded into location 50 H. (1000+FFB0= 50).

NOTE: If an error occurs while reading the tape (such as a checksum error), the monitor will immediately stop reading the tape, type '*(Cr)(Lf).' and await the next command. The operation may be retried by backing up the tape to any point before the last colon and issuing another R command, since each data word specifies the address at which it is to be loaded. The monitor will read up to the first colon it encounters, and then begin loading data.

Note that this means that, if you wish to change data in locations in memory, it is not necessary to regenerate an entirely new tape with the change; instead you may read in the original tape, then read in a patch tape which reloads only the erroneous locations.

Error Conditions:

1. If the bias address is greater than 16 bits, only the last 4 hex digits are used as the bias address.

Example: The command:

.R00FFB0 (Cr)

is equivalent to the command:

.RFFB0(Cr)

2. If an invalid character is present in the bias address, the monitor will immediately type '*(Cr)(lf).' and await the next command.

Example: If the user attempts to enter G00 as a bias address, the following will be printed:

4.2.11 S COMMAND (SUBSTITUTE MEMORY)

The S command is used to display and/or modify the contents of individual memory locations. It is used as follows:

1. Type an S, followed by the hexadecimal address of the first memory location you wish to display. Type space.

2. The data from the selected address is displayed, followed by a dash (-).

3. To modify memory, type in the new data followed by a space or a carriage return. If you do not wish to modify the contents of that location, do not type any data in, but only type a space or carriage return.

4. If a space was typed in step 3, the next memory location will be displayed as in step 2. If a carriage return was typed, operation will be returned to the System Monitor.

Example: The contents of the first four bytes of memory is 00 A1 CE FF. You wish to change it to 00 A3 CE 11.

.S0000Sp00Sp A1 -A3Sp CE -Sp FF -11Cr

User entries are unshaded. Printback is shaded.

Error Conditions:

1. If address is greater than 16 bits, or the data to be substituted is greater than 8 bits, only the last 4 or 2 hex digits respectively are used.

Example: The following sequence is equivalent to the previous example:

.S0AB0000Sp 00 -Sp A1 -BA3Sp CE -Sp FF -011Cr

2. If an invalid character is encountered, the monitor will immediately type '*(Cr)(lf). and await the next command.

4.2.12 X COMMAND (EXAMINE AND MODIFY REGISTERS)

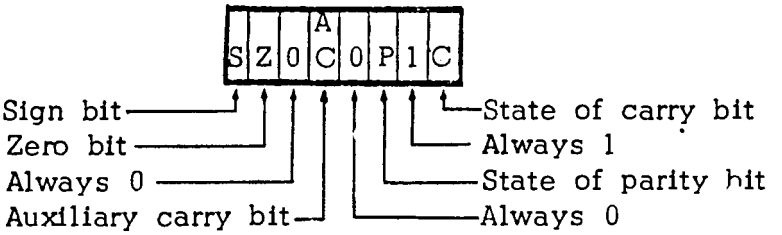
The format of the X command is:

X reg ident

Reg ident is a single character specifying a CPU register as follows:

A = A register
B = B register
C = C register
D = D register
E = E register
F = Flag byte, displayed in the form as it is stored by the instruction PUSH PSW
H = H register
L = L register
M = H and L registers combined (16 bits)
P = Program counter (16 bits)
S = Stack pointer (16 bits)

Note: The format of the flag byte F is:



Description: The X command is used to display and/or modify CPU registers. It operates similar to the S command, as follows:

1. Type an X, followed by the register identifier.
2. The data from the selected register is displayed, followed by a dash (-). Four hexadecimal digits are displayed for M, P, and S; two hex digits for the other register identifiers.
3. To modify the register, type in the new data followed by a space or a carriage return. If you do not wish to modify the register, type only the space or carriage return.
4. If a space was typed in step 3, the next register in alphabetical order is displayed. If carriage return was typed, the X command is terminated. If a space is typed after register S has been displayed, the command is terminated, this being the last register identifier in the list.

Example: The A, B, C, and D registers contain AAH, BBH, CCH, and DDH, respectively. You wish to change the B and C registers to 00H and FFH, respectively.

XASp AA-Sp BB-00Sp CC-FFSp DD-Cr

Note: Values set by the X-command will become the actual contents of the registers after execution of the next GO command.

The values displayed by the X-command are the contents of the registers prior to the execution of the last breakpoint set by the GO command. These displayed values, however, will reflect any changes of register "contents" made by the execution of X-commands since this last breakpoint.

Type an X followed by a carriage return. The contents of all internal registers will be printed out in the same form as above.

Note: Values set by the X-command will become the actual contents of the registers after execution of the next GO command.

The values displayed by the X-command are the contents of the registers prior to the execution of the last breakpoint set by the GO command. These displayed values, however, will reflect any changes of register "contents" made by the execution of X-commands since this last breakpoint.

Error Conditions:

1. If the data to be substituted is greater than 16 bits for registers M, P, S,or 8 bits for the other register identifiers, only the last 4 or 2 hex digits respectively are used.

2. If an invalid register identifier or character is encountered, the monitor will immediately type '*(Cr)(Lf).' and await the next command.

4.2.13 E COMMAND (END FILE)

The format of the E command is:

E address

Address is a valid 16 bit memory address.

Description: The E command causes an end-of-file mark and sixty null characters to be punched at the end of a hexadecimal output file. The end of file mark is hexadecimal record of length 00. (See Appendix D). If address is 0 or absent, the R command which loads the file will return control to the System Monitor. If address is non-zero, the R command will transfer control to that memory address immediately after loading the file.

4.2.14 W COMMAND (WRITE MEMORY)

The format of the W command is:

W low address ; high address

Low address is a valid 16 bit memory address.

High address is a valid 16 bit memory address equal to or greater than low address.

Description: The W command is used to output memory locations low address through high address to the system punch device in hexadecimal format. A series of W commands may be issued in order to punch various non-contiguous memory locations onto a continuous strip of tape.

Any series of W commands should be terminated with an E command in order to punch a termination character, so that when the tape is read it will be handled properly.

Example: If memory locations 1 through 3 contain 53F8EC, the command:

.W0001,0003(Cr)

produces:

:0300010053F8ECC5

(See Appendix D for an explanation of paper tape format.)

Error Conditions:

1. If low address or high address is greater than 16 bits, only the last 4 hex digits of the argument will be used as the address.

Example: The command:

WAB0010,100(Cr)

is equivalent to the command:

.W0010,100(Cr)

2. If low address is greater than high address, only the one byte at low address will be punched.

Example: The command:

.W10,0(Cr)

is equivalent to the command:

.W10,10(Cr)

3. Non-existent memory is equivalent to a string of bytes all containing FF H.

4. An invalid character in either address will cause the monitor to print '*(Cr)(lf).' and await the next command.

Example: If the user attempts to enter 3Z as low address, the following will be printed:

4.2.15 N COMMAND (NULL PUNCH)

The N command consists only of the letter N followed by a carriage return and causes 60 null characters to be punched.

4.2.16 T COMMAND (TRANSFER FROM PROM TO MEMORY)

The format of the T command is:

T address

Address is a valid 16 bit memory address.

Description: The T command causes the contents of a PROM in the front panel programming pocket to be transferred to memory beginning at address and continuing for 256 bytes.

Error Conditions:

1. If address is greater than 16 bits, only the last 4 hex digits will be used as the address.

Example: The command:

.TAB0100(Cr)

is equivalent to the command:

.T100(Cr)

2. If address specifies a non-existent memory range, no data is transferred.

3. If no PROM is present in the socket, 256 bytes of FF H will be transferred into memory.

Example: If no PROM is present, and the command:

.T100(Cr)

is issued, memory locations 0100 H through 01FF H will contain FF H.

4. If address contains an invalid character, the monitor will immediately type '*(Cr)(lf). and await the next command.

4.2.17 P COMMAND (PROGRAM PROM)

The format of the P command is:

P low address , high address , PROM address

Low Address is a valid 16 bit memory address.

High Address is a valid 16 bit memory address equal to or greater than low address.

PROM Address is an 8 bit data value.

Description: The P command causes the contents of memory from low address to high address to be programmed into a PROM module in the PROM programming socket.

Data are programmed into the PROM beginning at the PROM address.

Before attempting to program a PROM, ensure that the PROMPRGR POWER switch is ON, and that the PROM module is inserted firmly into the socket.

Error Conditions:

1. If low address or high address is greater than 16 bits, or if PROM address is greater than 8 bits, only the last 4 or 2 hex digits respectively will be used.

Example: The command:

.PAB0100,1FF,3FF(Cr)

is equivalent to the command

.P100,1FF,FF(Cr)

2. If low address is greater than high address, only one byte of data at low address will be transferred.

Example: The command:

.P400,300,0(Cr)

is equivalent to the command

.P400,400,0(Cr)

3. If low and high address refer to a non-existent memory range, a string of bytes containing FF H will be transferred to the PROM.

4. If an invalid character is typed in any address, the monitor will immediately type '*(Cr)(lf).' and await the next command.

Example: If the user attempts to type 3R as the PROM address, the following will be printed:

.P400,410,3R
*
.

5. If the PROM operation fails, the monitor will type a '$' and re-try the operation. Up to 3 retries will be performed, and, if still unsuccessful, the monitor will type the PROM address at which the failure occurred.

5.0 THE INTELLEC 8I TEXT EDITOR

The INTELLEC 8I Text Editor is used to create new source programs and to correct existing ones. It enables the user to create large amounts of alphanumeric text from either pre-existing paper tape or the assigned system CONSOLE device. Additions, deletions, and corrections may be made to the text on either a character-by-character or a line-by-line basis, and the resulting text may be output to either the assigned system CONSOLE device or the assigned system PUNCH device. For a complete description of the assignment of system I/O devices under the I/O System, see Section 4.2.1.

5.1 LOADING THE TEXT EDITOR

Prior to loading the Text Editor, system I/O devices should be assigned as desired by the user. If no assignments have been made, the Teletype unit will be used for all reading, printing, and punching operations. To load the Text Editor into the INTELLEC 8I memory, place the paper tape which includes the Text Editor onto the system READER device, as described in the appropriate subsection of Section 3. Enter the System Monitor, if you are not already using it, by loading C3H, 00 H, 38 H into the first three memory locations of the INTELLEC 8I and press the RESET button. (Manual loading of data is discussed in Section 3.2.2). Execute an R command; that is, type:

R (Cr)

The Text Editor source tape will automatically be loaded into the INTELLEC 8I memory.

When the paper tape has been loaded, the System Monitor will type a period in the left-hand column of the system CONSOLE device. Execute a Go To location 0010 command:

Type:

.G0010(Cr)

The Text Editor will then type:

INTELLEC 8 TEXT EDITOR, VERSION X.X

Start the system PUNCH device. The Text Editor will cause sixty null characters to be output to the PUNCH device and will then pause. Turn the PUNCH device off. The Text Editor will reply by typing an asterisk (*) in the left-hand column of the CONSOLE device; commands may now be entered.

5.2 TEXT EDITOR OPERATION AND COMMANDS

Text Editor operates on input from one of two sources: either the system CONSOLE device or the system READER device. The program stores the input into a memory buffer, called the workspace. A special register, called the buffer pointer, "points" to the location in the workspace from which operations are to be performed. The buffer pointer is always located between two characters. For example, suppose the workspace contains the following text (the buffer pointer is indicated by the arrow):

NOW IS THE TIME FOR ALL

In this case, the buffer pointer is located between the I and the M of TIME.

The Text Editor divides the contents of the workspace by the two classifications: characters and lines. A line, to the INTELLEC 8I Text Editor, is the space between two line feed characters. A character is a single ASCII character. CARRIAGE RETURN and LINE FEED are considered to be characters by the text editor, and can be manipulated in the same way as any other characters as in the following example:

The workspace contains the following data:

ABCDEFGH(Cr)(Lf)
IJKLMNOP(Cr)(Lf)
QRSTUVWXYZ(Cr)(Lf)

Text editor divides this data into lines as follows: line 1, consisting of ABCDEFGH(Cr)(Lf); line 2, consisting of IJKLMNOP(Cr)(Lf); and line 3 consisting of QRSTUVWXYZ(Cr)(Lf).

If the first LINE FEED character were removed, Text Editor would consider the workspace as 2 lines:

line 1	ABCDEFGH(Cr)IJKLMNOP(Cr)(Lf)
line 2	QRSTUVWXYZ(Cr)(Lf)

Text Editor commands are single letters typed into the CONSOLE device keyboard in response to the asterisk printed by the program. They may have arguments associated with them, and are terminated and executed with two ESCAPE or ALT MODE characters. These characters may differ for different devices; if they do not appear on a particular device, check its manual for the equivalent character.

```
*3D4L$$
       \_____________ALT MODE KEY STRUCK TWICE
```

The ESCAPE character (rather than CARRIAGE RETURN) is used to terminate commands because of the manner in which the Text Editor processes the CARRIAGE RETURN character. Carriage returns and line feeds are treated as data by the editor, so in order to create a clear distinction between data strings and command strings, ESCAPE is used as the command terminator while LINE FEED is used as the internal line terminator.

Note: When lines are being typed into the workspace, the Editor automatically supplies a LINE FEED with each CARRIAGE RETURN typed. It is not necessary to manually insert a LINE FEED unless text is prepared off-line.

The execution of a command may be terminated at any time by typing a BREAK character. This will cause the editor to cease command execution, and return to an input mode:

```
*757T$$
 NOW IS THE
 TIME FOR ALL
 GOOD MEN
 TO ( break typed by operator )
*
```

As described in Section 5.2.1 to 5.2.4, Editor commands may be divided into four functional groups: Input commands, output commands, data manipulation commands, and buffer pointer manipulation commands.

All text editor examples in Section 5 will assume that the workspace holds the following data (unless specifically stated otherwise):

```
NOW IS THE TIME FOR ALL GOOD MEN TO COME TO THE AID OF THEIR
COUNTRY
ABCDEFG
HIJKLMNOP
QRSTUV
WXYZ
123456
7890
```

The buffer pointer is assumed to be immediately preceding the word NOW, or at the beginning of the workspace.

Editor commands are presented in groups so that the reader will quickly identify commands by the purpose they serve in the normal sequence of source program generation or correction. Also, the format in which Editor commands are described differs from that used in Section 4 for System Monitor commands, since Editor commands are highly interactive and require more complex examples, most of which are in Sections 5.2.3, 5.2.4 and 5.2.5.

5.2.1 INPUT COMMANDS A (APPEND) AND I (INSERT)

Input commands cause text to be input to the workspace. There are two input commands: A, or Append, and I, or Insert.

A COMMAND (APPEND):

The format of the Append command is:

```
A$$
```

Description: The Append command causes text to be read from the assigned system READER device and to be appended to the workspace until one of the following conditions are met.

1. End of tape
2. End of file character (control-Z) read
3. Workspace full
4. 50 lines read

The Append command may be repeated until an entire input tape is read.

To execute an Append command, simply load the input tape onto the system READER device, turn the device on, and type an "A" followed by two ESCAPE characters on the CONSOLE device keyboard in response to the Text Editor asterisk. The tape will automatically begin to load in. Text Editor will type an asterisk at the left margin of the CONSOLE device when loading is finished. If the paper tape has not been loaded correctly, or if the READER device has not been turned on, Text Editor will issue an asterisk in the left-hand column, and the command must be reentered after clearing the error condition.

If there is no end-of-file on the tape, the Append will supply its own when the end of the tape is reached. In any case, no null characters or end-of-file characters will ever be put in the workspace; only the actual text characters will be put in the workspace.

I COMMAND (INSERT):

The format of the Insert command is:

I inserted text $$

Description: The Insert command causes text to be input from the CONSOLE device keyboard into the workspace. Text is inserted at the location pointed to by the buffer pointer and the buffer pointer is positioned after the last character of the inserted text.

In use, the Insert command itself is followed by an alphanumeric argument made up of the text to be inserted. For example, a typical appearance of the Insert command might be:

*INOW IS THE TIME FOR ALL GOOD

In this case, executing the I command would cause NOW IS THE TIME FOR ALL GOOD to be inserted into the workspace at the location of the buffer pointer. The buffer pointer would then be positioned immediately after the D in GOOD.

An example showing the relationship of the Insert command to the buffer pointer is given below.

The workspace originally contained the following:

THE INTELLEC 8 IS A COMPUTER

DESIGNED FOR DEVELOPMENT OF MICROCOMPUTERS

The following command was issued:

*IESPECIALLY (Sp) (Cr) (Lf)$$

The workspace now contains the following:

THE INTELLEC 8 IS A COMPUTER

DESIGNED ESPECIALLY

FOR DEVELOPMENT OF MICROCOMPUTERS

Note that the inclusion of the CARRIAGE RETURN and LINE FEED characters causes the formation of an entirely new line. If those characters had been omitted, the workspace would contain:

```
THE INTELLEC 8 IS A COMPUTER
DESIGNED ESPECIALLY FOR DEVELOPMENT OF MICROCOMPUTERS
```

The argument to an Insert command may be of any length up to the number of character spaces remaining in the workspace, and may be made up of any characters except the ESCAPE, ALT MODE, or BREAK characters.

When the inserted text is long enough to fill the workspace, the Text Editor stops echoing the inserted characters, instead echoing the BELL character. The operator should then delete characters by using the RUBOUT key, terminate the command, and either store the text on backup storage or edit the existing text as desired.

5.2.2 BUFFER POINTER MANIPULATION COMMANDS B (BEGINNING), C (CHARACTER), L (LINE), Z (END OF WORKSPACE)

Buffer pointer manipulation commands move the buffer pointer to different locations in the workspace, allowing operations to take place at any specified point in the workspace. There are four buffer pointer manipulation commands: B, or Beginning; C, or Character; L, or Line; and Z, or end of workspace.

B COMMAND (BEGINNING):

The format of the Beginning command is:

```
B$$
```

Description: The B, or Beginning, command moves the buffer pointer to the beginning of the workspace. This is useful when data is to be inserted at the front of the workspace or in order to type out the entire contents of the workspace.

Z COMMAND (END OF WORKSPACE):

The format of the End of Workspace command is:

Z$$

Description: The Z command is used to position the buffer pointer to the end of the workspace. This command is used before appending text to the end of the workspace.

C COMMAND (CHARACTER):

The format of the Character command is:

nC$$

n is a decimal number from -254 to +255. If not in this range, n is evaluated modulo 256. If not present, n is assumed to be positive 1.

Description: The C or Character command moves the buffer pointer forward or backward the number of characters specified by n. A negative argument causes the buffer pointer to move backward, and a positive argument causes the buffer pointer to move forward. If n is greater than the number of characters between the buffer pointer and the end (or beginning) of the workspace, the buffer pointer is moved to the end (or beginning) of the workspace. If n is 0, no movement occurs.

Example: Suppose the workspace contains:

(Buffer pointer is indicated by the arrow).

A command of 3C would move the buffer pointer to between the O and P. A command of -4C would move it to between the H and I. A command of 10C would move the buffer pointer to the end of the workspace; a command of -20C would move it to the beginning of the workspace.

L COMMAND (LINE):

The format of the Line command is:

nL$$

n is a decimal number from -254 to +255. If not in this range, n is evaluated modulo 256. If not present, n is assumed to be positive 1.

Description: The L or Line command moves the buffer pointer the number of lines specified by n. A positive argument causes the buffer pointer to move forward, and a negative argument causes the buffer pointer to move backward. An argument of 0 causes the buffer pointer to move backward to the first previous LINE FEED, i.e., the beginning of the current line. If n is greater than the number of lines between the buffer pointer and the end (or beginning) of the workspace, the buffer pointer is moved to the end (or beginning) of the workspace.

Text Editor considers a line to be a character string ending with a LINE FEED character:

ABCDEFGHIJKLMNOP(Cr) is not a line, as no LINE FEED character exists.

ABCDEFG(Cr)(Lf) is a line. Note that the text editor will automatically supply a LINE FEED with a CARRIAGE RETURN. It is not necessary to manually insert a LINE FEED unless text is prepared off-line.

Numerous examples of Buffer Pointer manipulation commands use are given in Section 5.2.3 and 5.2.4.

5.2.3 OUTPUT COMMANDS T (TYPE), W (WRITE), E (END), N (NULL)

Output commands cause the text in the workspace to be output to either the system CONSOLE device or the system PUNCH device, where it is either printed or punched, depending upon the command. There are four output commands: T, or Type; W, or Write; E, or End; and N, or Null.

T COMMAND (TYPE)

The format of the Type command is:

nT$$

n is a decimal number from -254 to +255. If n is out of range, it is evaluated modulo 256. If not present, n is assumed to be positive 1.

Description: The T, or Type command causes the number of lines specified by n to be output to the system CONSOLE device. Typing starts at the current location of the buffer pointer. n indicates the number of lines to be typed, if positive, or the number of previous lines to be typed if negative. If 0, the characters from the previous LINE FEED to the current buffer pointer location will be typed. If n is greater than the number of lines existing after (or before) the buffer pointer, only the existing lines are typed.

EXAMPLE 1: TYPE OUT

Note that for this example, the buffer pointer is initially in front of the sixth line in the workspace.

```
(1) *T$$
    WXYZ
(2) *-5T$$
    NOW IS THE TIME FOR ALL GOOD MEN TO COME TO THE AID OF THEIR
    COUNTRY
    ABCDEFG
    HIJKLMNOP
    QRSTUV
(3) *-4T$$
    COUNTRY
    ABCDEFG
    HIJKLMNOP
    QRSTUV
(4) *4T$$
    WXYZ
    123456
    7890
(5) *3T$$
    WXYZ
    123456
(6) 7890*
```

(1) T command - types one line after buffer pointer.

(2) -5T - types the 5 lines preceding the buffer pointer.

(3) -4T - types the 4 lines preceding the buffer pointer.

(4) 4T - types the 4 lines after the buffer pointer: Note that if the existing number of lines is less than the argument, only the existing line will be typed.

(5) 3T - types the 3 lines after the buffer pointer.

(6) Control is returned to Editor. (Note that, since the line "7890" does not end with a Cr Lf the asterisk is printed on the same line).

W COMMAND (WRITE):

The format of the Write command is:

nW$$

n is a decimal number from -254 to +255. A negative number is treated as if it were positive by this command. n is evaluated modulo 256. If n is not present, it is assumed to be positive 1.

Description: The W, or Write command causes the specified number of lines to be output to the system PUNCH device. If the Teletype is assigned as the PUNCH device, the lines will be printed as well as punched.

EXAMPLE 1: PUNCH 4 LINES

```
(1) *4W$$
(2) START PUNCH, TYPE CHAR
(3) NOW IS THE TIME FOR ALL GOOD MEN TO COME TO THE AID OF THEIR
    COUNTRY
    ABCDEFG
    HIJKLMNOP
(4) *4T$$
(5) QRSTUV
    123456
(6) 7890*
```

(1) W command--punch 4 lines.

(2) Typed by Editor only if the teletype is assigned as the system PUNCH device. Allows punch to be started. Any character may be input to start punching.

(3) 4 lines are typed and punched, then Editor pauses for tape punch shut-off, if the teletype is assigned as the system PUNCH device.

(4) T command -- types 4 lines.

(5) 4 lines typed -- new beginning of workspace.

(6) Control returned to Editor.

EXAMPLE 2: NEGATIVE ARGUMENT

*-1W$$

NOW IS THE TIME FOR ALL GOOD MEN TO COME TO THE AID OF THEIR
*

Note that the argument is -1, but +1 lines are typed/punched since negative arguments are treated as positive by this command.

E COMMAND (END):

The format of the End command is:

E$$

Description: The E, or End command causes the entire workspace to be output to the system PUNCH device, the workspace to be cleared, the remaining input on the input tape to be copied onto the PUNCH device, and the Editor to be reinitialized. If the Teletype is assigned as the system PUNCH device, the output will be printed as well as punched.

EXAMPLE: E COMMAND

```
(1)  *E$$
(2)  START PUNCH, TYPE CHAR
     NOW IS THE TIME FOR ALL GOOD MEN TO COME TO THE AID OF THEIR
     COUNTRY
     ABCDEFG
(3)  HIJKLMNOP
     QRSTUV
     WXYZ
     123456
     7890
(4)
(5)  INTELLEC 8 TEXT EDITOR, VERSION X.X
     START PUNCH, TYPE CHAR
(6)  *
```

(1) E Command -- initiates punching or workspace.

(2) First line typed only if teletype is assigned as the system PUNCH device. Allows punch to be turned on. Any character may be input to start punching.

(3) Workspace is output to the system PUNCH device. Note that if there is a paper tape in the system READER device, and if the READER device is turned on, the paper tape would be appended to the end of the workspace output.

(4) A character must be typed to give control back to Text Editor. Turn punch off before returning control to the Text Editor.

(5) Text Editor is initialized and sixty null characters are punched. The second line is typed only if the TTY is the system PUNCH device.

(6) Control is passed to the Editor.

N COMMAND (NULL):

The format of the Null command is:

N$$

Description: The N, or Null command causes sixty null characters to be output to the system PUNCH device. This command may be used to punch leader or trailer paper tape.

EXAMPLE:

(1) *N$$
(2) START PUNCH, TYPE CHAR
(3)

(1) N command - initiates punching
(2) Typed only if the teletype is assigned as the system PUNCH device. Allows PUNCH device to be turned on. After character is typed, Text Editor punches sixty null characters, and pauses to allow the PUNCH device to be turned off. Another character must be typed to return control to Text Editor.
(3) Control is passed to Editor.

5.2.4 DATA MANIPULATION COMMANDS D (DELETE), F(FIND), S (SUBSTITUTE), K(KILL)

Data manipulation commands are used to actually do the editing of the workspace material. Characters or lines may be deleted, changed or searched out. There are four data manipulation commands: D, or Delete; F, or Find, K, or Kill, and S, or Substitute.

D COMMAND (DELETE):

The format of the Delete command is:

nD$$

n is a decimal number from -254 to +255. If not in this range, n is evaluated modulo 256. If not present, n is assumed to be positive 1.

Description: The D, or Delete command causes a specified number of characters to be deleted from the workspace. The numeric argument which precedes the command determines the number of characters to be deleted, and its sign determines which direction is taken. A negative argument deletes characters preceding the buffer pointer, and a positive argument deletes characters following the buffer pointer. If n is 0, no action occurs. If n is greater than the number of characters between the buffer pointer and the end (or beginning) of the workspace, the appropriate characters are deleted and the buffer pointer is left at the end (or beginning) of the workspace.

Consider the following text in the workspace:

If the command 4D were executed, the end result would be:

COMPUTER PROGRA

If the command -6D were executed, the end result would be:

COMPUTER MMER

(Remember, the space is considered to be a character by the Editor).

EXAMPLE 1:

```
(1)  *3L$$
(2)  *4C$$
(3)  *-2D$$
(4)  *B$$
(5)  *4T$$
     NOW IS THE TIME FOR ALL GOOD MEN TO COME TO THE AID OF THEIR
(6)  COUNTRY
     ABCDEFG
     HILMNOP
(7)  *
```

(1) Buffer pointer is moved three lines down; i.e., to the beginning of HIJKLMNOP
(2) Buffer pointer is moved forward four characters; i.e., to just before L.
(3) Two characters immediately before the buffer pointer are deleted.
(4) Buffer pointer is moved to the beginning of the workspace.
(5) Four lines are typed, to observe the changes made in steps 1-3.
(6) Note that J and K were deleted.
(7) Editor is again ready to accept commands.

EXAMPLE 2:

```
(1)  *2L$$
(2)  *3C$$
(3)  *3D$$
(4)  *B$$
(5)  *3T$$
     NOW IS THE TIME FOR ALL GOOD MEN TO COME TO THE AID OF THEIR
(6)  COUNTRY
     ABCG
(7)  *
```

(1) Buffer pointer is moved two lines down to the beginning of ABCDEFG.
(2) Buffer pointer is moved three characters forward.
(3) Three characters are deleted.
(4) The buffer pointer is moved to the beginning of the workspace.
(5) Three lines are typed.
(6) Note the deletion of D, E and F.
(7) Editor is ready to accept commands.

K COMMAND (KILL):

The format of the Kill command is:

nK$$

n is a decimal number from -254 to +255. If not in this range, n is evaluated modulo 256. If not present, n is assumed to be positive 1.

Description: The K, or Kill command performs the same operation as the D command, except that it works on a line-by-line basis instead of a character-by-character basis. If n is 0, the characters from the buffer pointer to the first previous line feed will be deleted. If n is greater than the number of lines between the buffer pointer and the end (or beginning) of the workspace, the lines will be deleted and the buffer pointer will be at the end (or beginning) of the workspace.

EXAMPLE 1:

```
(1)  *2K$$
(2)  *3T$$
     ABCDEFG
(3)  HIJKLMNOP
     QRSTUV
(4)  *1L$$
(5)  *2K$$
(6)  *B$$
(7)  *3T$$
     ABCDEFG
(8)  VWXYZ
     123456
(9)  *
```

(1) Two lines are deleted.
(2) Three lines are typed.
(3) Note that NOW IS THE TIME FOR ALL GOOD MEN TO COME TO THE AID OF THEIR and COUNTRY have been deleted.
(4) The buffer pointer is moved down one line.
(5) Two lines are deleted.
(6) The buffer pointer is moved to the beginning of the workspace.
(7) Three lines are typed.
(8) Note the deletion of HIJKLMNOP and QRSTUV.
(9) Editor is ready to accept more commands.

EXAMPLE 2:

```
(1) *4L$$
(2) *-2K$$
(3) *B$$
(4) *3T$$
    NOW IS THE TIME FOR ALL GOOD MEN TO COME TO THE AID OF THEIR
(5) COUNTRY
    QRSTUV
(6) *
```

(1) The buffer pointer is moved forward four lines; i.e., to the beginning of QRSTUV.
(2) The two lines preceding the buffer pointer are deleted.
(3) The buffer pointer is moved to the beginning of the workspace.
(4) Three lines are typed.
(5) Note the deletion of ABCDEFG and HIJKLMNOP
(6) Editor is ready to accept new commands.

F COMMAND (FIND):

The format of the Find command is:

Ftext$$

text is a string of length 16 characters or less, including any characters except ESCAPE, ALT MODE, or BREAK.

Description: The F, or Find command, causes the Editor to search for the first occurrence of a character string in the workspace. The string to be searched out appears as an alphanumeric argument after the initial F. The Editor will begin its search at the present location of the buffer pointer and will conclude upon reaching either of the following points:

(1) A match is found. The buffer pointer is then positioned immediately after the matched character string.

(2) The end of workspace is encountered. Text Editor then types the message "CANNOT FIND" and the search string on the system CONSOLE device. The buffer pointer is not affected. If the string to be found is greater than 16 characters, a match will never occur.

EXAMPLE 1:

NOTE: Line 2 has been changed to PARTY instead of COUNTRY, and the buffer pointer is an undetermined position.

```
(1)   *FPARTY$$
(2)   CANNOT FIND "PARTY"
(3)   *B$$
(4)   *FPARTY$$
(5)   *IAS WELL AS THEIR COUNTRY.$$
(6)   *B$$
(7)   *2T$$
(8)   NOW IS THE TIME FOR ALL GOOD MEN TO COME TO THE AID OF THEIR
      PARTYAS WELL AS THEIR COUNTRY.
(9)   *FPARTY$$
(10)  *I $$
(11)  *B$$
(12)  *2T$$
(13)  NOW IS THE TIME FOR ALL GOOD MEN TO COME TO THE AID OF THEIR
      PARTY AS WELL AS THEIR COUNTRY.
(14)  *
```

(1) Editor is told to search for the string "PARTY".
(2) "PARTY" was not found. Either it does not exist within the workspace or the buffer pointer was located after the last occurrence of "PARTY".
(3) The buffer pointer is moved to the beginning of the workspace.
(4) "PARTY" is searched for again.
(5) "PARTY" is found and "AS WELL AS. . ." is inserted immediately after it.
(6) The buffer pointer is reset to the beginning.
(7) Two lines are typed.

(8) Note that since the buffer pointer was left, after the search, at the end of "PARTY" and no space was inserted, "AS" is concatenated with "PARTY".
(9) "PARTY" is searched for again.
(10) A space is inserted immediately after "PARTY".
(11) The buffer pointer is reset.
(12) Two lines are typed.
(13) The new line is checked.
(14) Editor is ready to accept more commands.
(15) *FPARTY$$
(16) *10D$$
(17) *B$$
*2T$$
(18) NOW IS THE TIME FOR ALL GOOD MEN TO COME TO THE AID OF THEIR PARTYS THEIR COUNTRY.

(15) "PARTY" is searched for again.
(16) The ten characters following the buffer pointer are deleted.
(17) The first two lines are typed.
(18) Note that the first ten characters after the Y in PARTY are deleted, including spaces.

S COMMAND (SUBSTITUTE):

The format of the Substitute command is:

S search string $ substitute string $$

search string and substitute string are strings of characters including any characters except ALT MODE, ESCAPE or BREAK.

Description: The S or Substitute command searches the workspace for the first occurrence of a specified character string of up to 16 characters and substitutes another string for it, if the search is successful. The search begins at the present location of the buffer pointer, and ends either when the string is found, or at the end of the workspace, in which case the message "CANNOT FIND" and the search string is typed on the system CONSOLE device. If the search if successful, the buffer pointer is positioned after the substituted string. If the search is unsuccessful, the buffer pointer is unaffected.

If search string is greater than 16 characters, only the first 16 are used.

Even if substitute string is greater than 16 characters, the entire substitute string will replace the search string.

Example:

```
(1) *SCOUNTRY$PARTY$$
(2) *-1T$$
(3)  NOW IS THE TIME FOR ALL GOOD MEN TO COME TO THE AID OF THEIR
     PARTY
     *
```

(1) The workspace is searched for the string "COUNTRY" and, when "COUNTRY" is found, substitutes the string "PARTY" for it.
(2) The line immediately preceding the buffer pointer is typed.
(3) Note the occurrence of "PARTY" rather than "COUNTRY".

5.2.5 COMMAND STRINGS

Text Editor commands may be chained together to form command strings. Strings may be made up of any number of commands and will be executed as individual commands from left to right. An example of a command string is

```
*B3L1K4DICORRECTION
```

which would, in order of execution:

Position the buffer pointer at the beginning of the workspace;

Move it down three lines;

Delete one line;

Delete four characters;

Insert the string "CORRECTION" into the workspace.

Commands may optionally be separated from each other with ESCape or ALT MODE characters (echoed as dollar signs); S, F and I commands must be separated from other commands in this manner, for otherwise Text Editor would have no means of distinguishing between the text to be inserted or searched and the next command: a string such as

```
IINSERT3L4D
```

would cause INSERT3L4D to be placed into the workspace, while

```
IINSERT$3L$4D
```

would cause INSERT to be inserted, the buffer pointer to be advanced three lines and four characters to be deleted.

Example 1:

```
*B3T$$
NOW IS THE TIME FOR ALL GOOD MEN TO COME TO THE AID OF THEIR
COUNTRY
ABCDEFG
*
```

The command string B3T causes the buffer pointer to be reset to the beginning of the workspace and then types the three lines immediately after the buffer pointer. The net effect is to type the first three lines in the workspace.

Example 2:

```
      *4L$$
      *-2C$$
      *-4D$$
      *-2T$$
      COUNTRY
      ABCDEFG
(1)   HIJKL*B3L3T$$
      HIJKL
      ORSTUV
      WXYZ
(2)   *B4L-2CIMNOP$$
(3)   *B3L3T$$
      HIJKLMNOP
      ORSTUV
      WXYZ
      *
```

(1) The string B3L3T causes the third, fourth, and fifth lines to be typed.
(2) The string B4L-2XIMNOP causes the buffer pointer to be positioned immediately after the L in the third line (B4L-2C), and the string MNOP to be inserted. Note that a line is ended with the two characters CARRIAGE RETURN and LINE FEED.
(3) The first three lines are typed out.

The commands listed as 2 and 3 could have been combined effectively. The resulting command string B4L-2CIMNOP$B3L3T would cause the same series of operations to be performed as the two separate strings B4L-2CIMNOP and B3L3T. Note, however, that the I command is separated from the B command by an ESCape or ALT MODE character, echoed as a dollar sign.

5.2.6 USE OF TABS

The Text Editor allows the use of the horizontal tab character, (created by typing the CTRL and I keys simultaneously) wherever a space could be used. This allows the operator to produce a more readable listing. Tab stops are located every eight positions.

Example:

The editor command:

```
*ILABEL"tabMOVtabA,Btab;SpCOMMENTS$$
```

is printed as:

```
COL     0       1       2
01234567890123456789012345678 90

LABEL:  MOV     A,B     ; COMMENT
        JMP     HOME
```

5.2.7 COMMAND ITERATION

The Text Editor allows a specified command string to be automatically executed a specified number of times. This is done by command iteration.

In order to cause a command string to be automatically executed more than once, angle brackets (< and >) should be used to surround the command:

n< command string >$$

The number immediately preceding the left bracket (<), n, determines the number of times the command is executed. n is evaluated modulo 256.

EXAMPLE:

(1) ■4<IHELLO.CrLf
R>$B4T$$
(2) HELLO
HELLO
HELLO
HELLO
(3) *

(1) The command is entered. This command will insert the string HELLO. CrLf four successive times, move the buffer pointer to the beginning of the workspace, and type the first four lines of the workspace.
(2) The first four lines of the workspace are typed. Note that the string HELLO.CrLf has, indeed, been inserted four times.
(3) Control is returned to the Editor.

Command iterations may be nested up to eight levels deep, by placing a bracketed command string inside of another bracketed string.

EXAMPLE:

(1) ■2<IA$2< IB$>>0LT$$
(2) ABBABB
(3) ■

(1) The command is entered. This command will cause, in order, "A" to be inserted, "B" to be inserted twice, "A" to be inserted, "B" to be inserted twice more, the buffer pointer to be moved to the beginning of the line, and the line to be typed.
(2) The line is typed. Note that the command 2<IB$> caused B to be inserted twice each time it was encountered, and that the overall command IA$2<IB$> was executed twice.

(3) Control is returned to the Editor.

If command iterations are nested more than eight deep, the Text Editor will print the error message "ITERATION STACK FAULT" on the system CONSOLE device, and the command will have to be reentered with the error condition removed.

EXAMPLE:

```
(1) *2<IA$2<IB$2<IC$2<ID$2<IE$2<IF$2<IG$2<IH$2<II$>>>>>>>>>$$
(2) ITERATION STACK FAULT
(3) *2<IA$2<IB$2<IC$2<ID$2<IE$2<IF$2<IG$2<IHII$>>>>>>>$$
(4) *0L$T$$
(5) ABCDEFGHIIHIIGHIIHIIFGHIIHIIEFGHIIHIIDEFGHIIHIIGDEFGHIIHIBBCDEFGHIIHII
    ABCDEFGHIIHII
(6) *
```

(1) The command is entered. Note that there are nine levels of iteration.
(2) Text Editor types the error message, and terminates command execution.
(3) Text Editor types an asterisk. The new command is entered. Note that there are now only eight levels of iteration.
(4) The buffer pointer is reset, and the line is typed.
(5) The typed line.
(6) Control is returned to the Text Editor.

6.0 THE INTELLEC 8I ASSEMBLER

This section will deal with the loading and execution of the INTELLEC 8I assembler source tape. For more information on the assembly language itself, consult the 8080 Programmer's Manual. See Appendix A for a summary of pseudo operations and the assembly language instruction set.

6.1 LOADING THE ASSEMBLER

To load the Assembler into the INTELLEC 8I memory, place the paper tape containing the Assembler onto the system READER device as described in the appropriate subsection of Section 3. Ensure that the READER device is turned on. Enter the System Monitor, if it is not already running, by loading the data C3H, 00 H, and 38 H into the first three locations in memory, and pressing the RESET button. When System Monitor is running, assign I/O devices to the system READER, CONSOLE, LIST and PUNCH devices as desired. For complete details of I/O device assignment under the I/O System, see Section 4.2.1. Then execute an R command; that is, type:

.R(Cr)

The Assembler source tape will then be loaded into the INTELLEC 8I memory.

When the paper tape is completely loaded into memory, System Monitor will type a period (.) in the left-hand column of the CONSOLE device. When this occurs, enter a Go To 0010 command:

.G0010 (Cr)

The INTELLEC 8I Assembler will begin operations.

6.2 EXECUTION OF THE ASSEMBLER

The INTELLEC 8I Assembler is a two or three pass assembler, depending upon the devices selected as the system LIST and system PUNCH devices. If these devices can be operated independently, then two passes are necessary for complete assembly; that is, the input paper tape must be read in twice in order to produce the final paper tape containing the machine-coded instructions. If the LIST device and the PUNCH device cannot be operated independently, as is the case if the Teletype is

assigned to both devices, the Assembler operates as a three-pass assembler and the input paper tape must be read in three times.

When the Assembler begins operations, it will print P= on the CONSOLE device. Load the input paper tape into the READER device, make sure that the READER device is turned on, and type 1 on the CONSOLE device.

The input tape will be read in, and the assembler will process the first pass, which sets up the symbol tables for the program.

When the Assembler has finished processing the first pass, it will again print P= on the CONSOLE device. Reload the input paper tape on the READER device, and type in either 2 (if the LIST and PUNCH devices cannot be operated independently) or 4 (if the LIST and PUNCH devices may be operated independently). The input paper tape will be read in again, and the Assembler will begin processing the second pass.

If the second pass was started by typing 4 in response to the Assembler query, it will perform two functions: first, it will create a listing of the program, including any error messages which may have been generated during Assembly. This listing will be printed on the LIST device. Second, it will output the machine-coded instructions to the PUNCH device to create a hexadecimal format tape containing the assembled program.

If 2 was entered at the beginning of the second pass, then the second pass will only output the program listing to the LIST device. The Assembler will again print P= on the CONSOLE device. The input paper tape must be reloaded, and 3 typed on the CONSOLE device. The input paper tape will be read again, and the hexadecimal format machine-coded program will be output to the PUNCH device.

6.3 ASSEMBLER LIMITS

The following facts should be remembered while creating source programs for the INTELLEC 8I Assembler:

(1) There is no limit as to the number of characters in any one assembler statement; however only 72 characters per line will be printed on the teletype.

(2) There is no limit as to the number of characters in any one symbol; however, the first five characters of any symbol must be unique.

(3) The maximum number of parameters that may be associated with any macro is 126.

(4) Only a finite amount of memory is available to the assembler in which to store its symbol table. Therefore, assemblies containing excessive numbers of symbols and macros may cause an overflow of the symbol table, invalidating the assembly.

Each symbol requires 8 bytes of memory in the symbol table, and every character of every macro definition is stored in the symbol table. In addition, every macro reference requires some symbol table memory (the precise amount varies with the environment of the macro reference).

If assemblies are being made on an INTELLEC 8I system with limited memory, then, the macro definitions and number of symbols should be as small as possible.

6.4 SYNTAX RESTRICTIONS

The following rules must be observed when writing source programs for the INTELLEC 8I Assembler:

(1) Symbols which appear as names in EQU or SET operations must be defined before being used in expressions or operands.

Thus the instruction sequence:

```
FIRST:    DB      SYM*3
SYM       EQU     2
```

is invalid.

(2) A macro must be defined before any references to it are made. Thus the instruction sequence:

```
REF:      LOAD    A,B       ; MACRO REFERENCE
                  :
LOAD      MACRO   P1,P2     ; MACRO DEFINITION
                  :
          ENDM
```

is invalid.

(3) Macros may not be defined within other macro definitions; that is, a MACRO pseudo instruction may not appear between any MACRO and ENDM pseudo instructions.

Thus the sequence:

```
MAC1        MACRO
              .
              .
              .
MAC2        MACRO
              .
              .
              .
            ENDM
              .
              .
              .
            ENDM
```

is invalid.

(4) The parameters listed in the operand field of a MACRO pseudo-instruction may not be symbols previously defined in the assembly.

Thus the sequence:

```
P1:         EQU       5
              .
              .
              .
MAC1        MACRO     P1,P2
```

is invalid.

6.5 ASSEMBLER ERROR MESSAGES

Errors detected by the assembler are indicated by single letter codes printed at the teletype during pass 2. These codes are as follows:

A ADDRESS ERROR:

Description: This error indicates that the address referenced by a JUMP or CALL instruction is not in the range 0 to 65535.

Example:

```
JUMP        65536D      ; A ERROR
JUMP        -2          ; A ERROR
```

B BALANCE ERROR:

Description: This error indicates that the parentheses in an expression are unbalanced, or that the quotes in an ASCII string are unbalanced.

Example:

```
MVI     H,3*(2+(4)      ; B Error
DB      ''A'            ; B Error
```

E EXPRESSION ERROR:

Description: This error indicates a badly constructed expression. It usually occurs due to a missing operator, omitted comma, or a misspelled opcode.

Example:

```
MVI     H,3 (2+4)       ; E Error, Missing Operator
MVO     H,M             ; E Error, Mispelled Opcode
```

F FORMAT ERROR:

Description: This error indicates an error in the format of a statement. It is usually caused by a missing operand or an extraneous operand.

Example:

```
MOV     ,D              ; F Error, Missing Operand
MOV     A,B,C           ; F Error, Extraneous Operand
```

I ILLEGAL CHARACTER:

Description: This error indicates that an invalid ASCII character is present in the statement. It is also caused by a numeric character which is too big for the base of the number in which it occurs.

Example:

```
MVI     H,02B           ; I Error, 2 Invalid in Binary
MVI     H,79Q           ; I Error, 9 Invalid in Octal
```

M MULTIPLE DEFINITION:

Description: This error indicates that two or more labels exist which are identical or not unique in the first five characters.

NOTE: Identical labels generated by macro references are legal.

Example: The following segment of code is illegal:

```
LABEL1:     INC     B
            :
            :
LABEL2:     INC     C           ;M ERROR
```

N NESTING ERROR:

Description: This error indicates that an IF, ENDIF, MACRO, or ENDM statement is improperly nested.

Example: The statement:

```
            ENDIF
```

will cause an N error if no IF statement precedes it in the program.

P PHASE ERROR:

Description: This error indicates that the value of an element being defined changed between pass one and pass two of the assembly.

Example: The following segment of code will cause every label in the assembly to produce a P error:

```
            ORG     BEGIN
            :
            :
BEGIN       EQU     5
```

During pass one, the symbol BEGIN is undefined when the ORG is reached. The assembler will assume it to be 0, and begin assembling the program at 0. During pass two, the symbol BEGIN is equal to 5. Therefore the location assigned to every label in the program will have increased by 5, producing a P error.

Q QUESTIONABLE SYNTAX:

Description: This error is usually caused by omitting an opcode.

Example:

```
LOC         1234H,5AB3H         ;Opcode DW was omitted.
```

R REGISTER ERROR:

Description: This error indicates that a register specified for an operation is invalid for that operation.

Example:

```
        PUSH        A           ; R ERROR, A INVALID FOR PUSH
```

S STACK OVERFLOW:

Description: This error indicates that the assembler's internal expression evaluation stack became too large and overflowed the memory available to the assembler. It may be caused by using extremely long character strings, too many nested macros, too many nested IF statements, or expressions which are too complex.

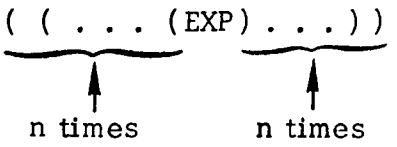
Example: A nested IF statement is one which occurs between another IF - ENDIF pair. Thus long sequences of the form:

```
IF          EXP
:
IF          EXP
:
IF          EXP
:
ENDIF
ENDIF
ENDIF
:
```

may cause an S error.

The assembler can evaluate complex expressions as long as they do not contain unnecessary parentheses.

An expression of the form:



will cause an S error when n becomes large enough.

T TABLE OVERFLOW:

Description: This error indicates that the assembler's symbol table space has been exhausted. This may be caused by using too many symbols, overly lengthly macro definitions, or too many macro references in an assembly.

U UNDEFINED IDENTIFIER:

Description: This error indicates that a symbol used in an operand field was never defined by appearing in the label field of another instruction.

Example: If the statement

```
        MVI     H,LAB1
```

appears is an assembly, and the symbol LAB1 does not appear in the label field of any other statement, it will cause a U error.

V ILLEGAL VALUE:

Description: This error indicates that the value of an operand or expression exceeds the range required for a particular operation.

Example: The statement:

```
        RST  8
```

will cause a V error, because the operand of a RST instruction must be in the range 0 to 7.

The statements:

```
                ORG     256
LOC:            INCR    B
                :
                :
                MVI     H,LOC
```

will cause a V error, since the value of the second operand of an MVI instruction must be an 8 bit quantity, while the value of LOC is a 16 bit address which cannot be held in 8 bits.

APPENDIX A

-- INSTRUCTION SUMMARY --

This appendix provides a summary of 8080 assembly language instructions. Abbreviations used are as follows:

A	The accumulator (register A)
A_n	Bit n of the accumulator contents, where n may have any value from 0 to 7 and 0 is the least significant (rightmost) bit.
ADDR	Any memory address
Aux. carry	The auxiliary carry bit
Carry	The carry bit
CODE	An operation code
DATA	8 bits (one byte) of data
DATA16	16 bits (2 bytes) of data
DST	Destination register or memory byte
EXP	A constant or mathematical expression
INTE	The 8080 interrupt enable flip-flop
LABEL:	Any instruction label
M	A memory byte
Parity	The parity bit
PC	Program Counter
PCH	The most significant 8 bits of the program counter
PCL	The least significant 8 bits of the program counter
REGM	Any register or memory byte

RP	**A register pair. Legal register pair symbols are:** **B for registers B and C** **D for registers D and E** **H for registers H and L** **SP for the 16 bit stack pointer** PSW for condition bits and register A
RP1	**The first register of register pair RP**
RP2	**The second register of register pair RP.**
sign	**The sign bit**
SP	**The 16-bit stack pointer register**
SRC	**Source register or memory byte**
zero	**The zero bit**
XY	**The value obtained by concatenating the values X and Y**
[ ]	**An optional field enclosed by brackets**
( )	**Contents of register or memory byte enclosed by parentheses**
←	**Replace value on lefthand side of arrow with value on right-hand side of arrow**

CARRY BIT INSTRUCTIONS

Format:

[LABEL:] CODE

CODE	DESCRIPTION		
STC	(carry) ←	1	Set carry
CMC	(carry) ←	$\overline{\text{carry}}$	Complement carry

Condition bits affected: Carry

SINGLE REGISTER INSTRUCTIONS

Format:

```
[LABEL:]    INR     REGM
            -or-
[LABEL:]    DCR     REGM
            -or-
[LABEL:]    CMA
            -or-
[LABEL:]    DAA
```

Code	Description	
INR	(REGM) ← (REGM)+1	Increment register REGM
DCR	(REGM) ← (REGM)-1	Decrement register REGM
CMA	(A) ← $\overline{(A)}$	Complement accumulator
DAA	If $(A_0\text{-}A_3) > 9$ or (aux. carry)=1, (A) ← (A)+6 Then if $(A_4\text{-}A_7) > 9$ or (carry)= 1 (A) = (A) + 6 * 2^4	Convert accumulator contents to form two decimal digits

Condition bits affected:
INR, DCR : Zero, sign, parity
CMA : None
DAA : Zero, sign, parity, carry, aux. carry

NOP INSTRUCTION

Format:

```
[LABEL:]    NOP
```

Code	Description
NOP	- - - - - - - No operation

Condition bits affected: None

DATA TRANSFER INSTRUCTIONS

Format:

```
[LABEL:]    MOV     DST,SRC
            -or-
[LABEL:]    CODE    RP
```

NOTE: SRC and DST not both = M

NOTE: RP = B or D

Code	Description	
MOV	(DST) ← (SRC)	Load register DST from register SRC
STAX	((RP)) ← (A)	Store accumulator at memory location referenced by the specified register pair
LDAX	(A) ← ((RP))	Load accumulator from memory location referenced by the specified register pair

Condition bits affected: None

REGISTER OR MEMORY TO ACCUMULATOR INSTRUCTIONS

Format:

```
[LABEL:]    CODE        REGM
```

Code	Description	
ADD	(A) ← (A)+(REGM)	Add REGM to accumulator
ADC	(A) ← (A)+(REGM)+(carry)	Add REGM to accumulator with carry
SUB	(A) ← (A)-(REGM)	Subtract REGM from accumulator
SBB	(A) ← (A)-(REGM)-(carry)	Subtract REGM from accumulator with borrow
ANA	(A) ← (A) AND (REGM)	AND accumulator with REGM
XRA	(A) ← (A) XOR (REGM)	EXCLUSIVE-ORaccumulator with REGM

Code	Description	
ORA	(A) ← (A) OR (REGM)	OR accumulator with REGM
CMP	Condition bits set by (A)-(REGM)	Compare REGM with accumulator

Condition bits affected:

ADD, ADC, SUB, SBB: Carry, sign, zero, parity, aux. carry
ANA, XRA, ORA: Sign, zero, parity. Carry is zeroed.
CMP: Carry, sign, zero, parity, aux. carry. Zero set if (A)=(REGM)
Carry reset if (A) < (REGM)
Carry set if (A) ≥ (REGM)

ROTATE ACCUMULATOR INSTRUCTIONS

Format:

[LABEL:] CODE

Code	Description	
RLC	(carry) ← A_7, A_{n+1}, ← A_n, A_0 ← A_7	Set carry = A_7, rotate accumulator left
RRC	(carry) ← A_0, A_n ← A_{n+1}, A_7 ← A_0	Set carry = A_0, rotate accumulator right
RAL	A_{n+1} ← A_n, (carry) ← A_7, A_0 ← (carry)	Rotate accumulator left through the carry
RAR	A_n ← A_{n+1}, (carry) ← A_0, A_7 ← (carry)	Rotate accumulator right through carry

Condition bits affected: Carry

REGISTER PAIR INSTRUCTIONS

Format:

[LABEL:] CODE1 RP
-or-
[LABEL:] CODE2

Note: For PUSH and POP, RP=B,D,H, or PSW
For DAD, INX, and DCX, RP=B,D,H, or SP

Code1	Description	
PUSH	((SP)-1) ← (RP1), ((SP)-2) ← (RP2), (SP) ← (SP)-2	Save RP on the stack RP=A saves accumulator and condition bits.
POP	(RP1) ← ((SP)+1), (RP2) ← ((SP)), (SP) ← (SP)+2	Restpre RP from the stack RP=A restores accumulator and condition bits.
DAD	(HL) ← (HL) + (RP)	Add RP to the 16-bit number in H and L.
INX	(RP) ← (RP)+1	Increment RP by 1
DCX	(RP) ← (RP)-1	Decrement RP by 1
Code2	**Description**	
XCHG	(H) ↔ (D), (L) ↔ (E)	Exchange the 16 bit number in H and L with that in D and E.
XTHL	(L) ↔ ((SP)), (H) ↔ ((SP)+1)	Exchange the last values saved in the stack with H and L.
SPHL	(SP) ← (H):(L)	Load stack pointer from H and L.

Condition bits affected:

PUSH, INX, DCX, XCHG, XTHL, SPHL: None
POP : If RP=PSW, all condition bits are restored from the stack, otherwise none are affected.
DAD : Carry

IMMEDIATE INSTRUCTIONS

Format:

```
[LABEL:]    LXI     RP, DATA16
            -or-
[LABEL:]    MVI     REGM, DATA
            -or-
[LABEL:]    CODE    REGM
```

Note: RP=B,D,H, or SP

CODE	DESCRIPTION	
LXI	(RP)←— DATA 16	Move 16 bit immediate Data into RP
MVI	(REGM)←———DATA	Move immediate DATA into REGM
ADI	(A)←— (A) + DATA	Add immediate data to accumulator
ACI	(A)←— (A) + DATA + (carry)	Add immediate data to accumulator with carry
SUI	(A)←— (A) - DATA	Subtract immediate data from accumulator
SBI	(A)←— (A) - DATA - (carry)	Subtract immediate data from accumulator with borrow
ANI	(A)←— (A) AND DATA	AND accumulator with immediate data
XRI	(A)←— (A) XOR DATA	EXCLUSIVE-OR ccumulator with immediate data
ORI	(A)←— (A) OR DATA	OR accumulator with immediate data
CPI	Condition bits set by (A)-DATA	Compare immediate data with accumulator

Condition bits affected:

LXI, MVI: None
ADI, ACI, SUI, SBI: Carry, sign, zero, parity, aux. carry
ANI, XRI, ORI: Zero, sign, parity. Carry is zeroed.
CPI: Carry, sign, zero, parity, aux. carry.
Zero set if (A) = DATA
Carry reset if (A) < DATA
Carry set if (A) $\geqslant$ DATA

DIRECT ADDRESSING INSTRUCTIONS

Format:

[LABEL:] CODE ADDR

CODE	DESCRIPTION	
STA	(ADDR) ←——— (A)	Store accumulator at location ADDR
LDA	(A) ←— (ADDR)	Load accumulator from location ADDR
SHLD	(ADDR) ← (L), (ADDR+1) ← (H)	Store L and H at ADDR and ADDR+1
LHLD	(L)←— (ADDR), (H)← (ADDR+1)	Load L and H from ADDR and ADDR+1

Condition bits affected: None

JUMP INSTRUCTIONS

Format:

[LABEL:] PCHL

-or-

[LABEL:] CODE ADDR

CODE	DESCRIPTION	
PCHL	(PC)←— (HL)	Jump to location specified by register H and L
JMP	(PC)———ADDR	Jump to location ADDR
JC	If (carry) = 1, (PC)←— ADDR If (carry) = 0, (PC)←— (PC)+3	Jump to ADDR if carry set
JNC	If (carry) = 0, (PC)←— ADDR If (carry) = 1, (PC)←— (PC)+3	Jump to ADDR if carry reset
JZ	If (zero) = 1, (PC)←— ADDR If (zero) = 0, (PC)←— (PC)+3	Jump to ADDR of zero set
JNZ	If (zero) = 0, (PC)←— ADDR If (zero) = 1, (PC)←— (PC)+3	Jump to ADDR if zero reset
JP	If (sign) = 0, (PC)←— ADDR If (sign) = 1, (PC)←— (PC)+3	Jump to ADDR if plus
JM	If (sign) = 1, (PC)←— ADDR If (sign) = 0, (PC)←— (PC)+3	Jump to ADDR if minus
JPE	If (parity)= 1, (PC)←— ADDR If (parity)= 0, (PC)←— (PC)+3	Jump to ADDR if parity even
JPO	If (parity)= 0, (PC)←— ADDR If (parity)= 1, (PC)←— (PC)+3	Jump to ADDR if parity odd

Condition bits affected: None

CALL INSTRUCTIONS

Format:

[LABEL:] CODE ADDR

CODE	DESCRIPTION
CALL	((SP)-1)← (PCH), ((SP)-2)← (PCL), (SP)← (SP)+2, (PC) ← ADDR Call subroutine and push return address onto stack
CC	If (carry) = 1, ((SP)-1)← (PCH), ((SP)-2)← (PCL), (SP) ← (SP)+2, (PC) ← ADDR If (carry) = 0, (PC) ← (PC)+3 Call subroutine if carry set
CNC	If (carry) = 0, ((SP)-1)← (PCH), ((SP)-2)← (PCL), (SP)← (SP)+2, (PC) ← ADDR If (carry) = 1, (PC) ← (PC)+3 Call subroutine if carry reset
CZ	If (zero) = 1, ((SP)-1)-(PCH), ((SP)-2)← (PCL), (SP)← (SP)+2, (PC)← ADDR If (zero) = 0, (PC) ← (PC)+3 Call subroutine if zero set
CNZ	If (zero) = 0, ((SP)-1) ← (PCH), ((SP)-2)← (PCL), (SP)← (SP)+2, (PC) ← ADDR If (zero) = 1, (PC) ← (PC)+3 Call subroutine if zero reset
CP	If (sign) = 0, ((SP)-1)← (PCH), ((SP)-2)← (PCL), (SP)← (SP)+2, (PC) ← ADDR If (sign) = 1, (PC) ← (PC)+3 Call subroutine if sign plus
CM	If (sign) = 1, ((SP)-1)← (PCH), ((SP)-2)← (PCL), (SP)← (SP)+2, (PC) ← ADDR If (sign) = 0, (PC) ← (PC)+3 Call subroutine if sign minus
CPE	If (parity)= 1, ((SP)-1)← (PCH), ((SP)-2)← (PCL), (SP)← (SP)+2, (PC) ← ADDR If (parity)= 0, (PC) ← (PC)+3 Call subroutine if parity even
CPO	If (parity)= 0, ((SP)-1)← (PCH), ((SP)-2)← (PCL), (SP)← (SP)+2, (PC)← ADDR If (parity)= 1, (PC)← (PC)+3 Call subroutine if parity odd

Condition bits affected: None

RETURN INSTRUCTIONS

Format:

[LABEL:] CODE

CODE	DESCRIPTION
RET	(PCL)←((SP)), (PCH)←((SP)+1), (SP)←(SP)+2 Return from subroutine
RC	If (carry) = 1, (PCL)←((SP)), (PCH)←((SP)+1), (SP)←(SP)+2 If (carry) = 0, (PC)←(PC)+3 Return if carry set
RNC	If (carry) = 0, (PCL)←((SP)), (PCH)←((SP)+1), (SP)←(SP)+2 If (carry) = 1, (PC)←(PC)+3 Return if carry reset
RZ	If (zero) = 1, (PCL)←((SP)), (PCH)←((SP)+1), (SP)←(SP)+2 If (zero) = 0, (PC)←(PC)+3 Return if zero set
RNZ	If (zero) = 0, (PCL)←((SP)), (PCH)←((SP)+1), (SP)←(SP)+2 If (zero) = 1, (PC)←(PC)+3 Return if zero reset
RM	If (sign) = 1, (PCL)←((SP)), (PCH)←((SP)+1), (SP)←(SP)+2 If (sign) = 0, (PC)←(PC)+3 Return if minus
RP	If (sign) = 0, (PCL)←((SP)), (PCH)←((SP)+1), (SP)←(SP)+2 If (sign) = 1, (PC)←(PC)+3 Return if plus
RPE	If (parity)= 1, (PCL)←((SP)), (PCH)←((SP)+1), (SP)←(SP)+2 If (parity)= 0, (PC)←(PC)+3 Return if parity even
RPO	If (parity)= 0, (PCL)←((SP)), (PCH)←((SP)+1), (SP)←(SP)+2 If (parity)= 1, (PC)←(PC)+3 Return if parity odd

Condition bits affected: None

RST INSTRUCTION

Format:

[LABEL:] RST EXP

Note: 0 EXP 7

CODE	DESCRIPTION
RST	((SP)-1)←(PCH), ((SP)-2)←(PCL), (SP)←(SP)+2 (PC)←0000000000EXP000B Call subroutine at address specified by EXP

Condition bits affected: None

INTERRUPT FLIP FLOP INSTRUCTIONS

Format:

[LABEL:] CODE

CODE	DESCRIPTION	
EI	(INTE) ← 1	Enable the interrupt system
DI	(INTE) ← 0	Disable the interrupt system

Condition bits affected: None

INPUT/OUTPUT INSTRUCTIONS

Format:

[LABEL:] CODE EXP

CODE	DESCRIPTION		
IN	(A) ←	input device	Read a byte from device EXP into the accumulator
OUT	output device ←	(A)	Send the accumulator contents to device EXP

Condition bits affected: None

HLT INSTRUCTION

Format:

[LABEL:] HLT

CODE	DESCRIPTION	
HLT	----------	Instruction execution halts until an interrupt occurs.

Condition bits affected: None

PSEUDO - INSTRUCTIONS

ORG PSEUDO - INSTRUCTION

Format:

ORG EXP

Code	Description	
ORG	LOCATION COUNTER ← EXP	Set Assembler location counter to EXP

EQU PSEUDO- INSTRUCTION

Format:

NAME EQU EXP

Code	Description	
EQU	NAME ← EXP	Assign the value EXP to the symbol NAME

SET PSEUDO - INSTRUCTION

Format:

NAME SET EXP

Code	Description	
SET	NAME ⟵ EXP	Assign the value EXP to the symbol NAME., which may have been previously SET.

END PSEUDO - INSTRUCTION

Format:

END

Code	Description
END	End the assembly.

CONDITIONAL ASSEMBLY PSEUDO - INSTRUCTIONS

Format:

IF EXP

-and-

ENDIF

Code	Description
IF	If EXP =0, ignore assembler statements until ENDIF is reached. Otherwise, continue assembling statements.
ENDIF	End range of preceding IF.

MACRO DEFINITION PSEUDO - INSTRUCTIONS

Format:

NAME MACRO LIST

-and-

ENDM

Code	Description
MACRO	Define a macro named NAME with parameters LIST
ENDM	End macro definition

APPENDIX B

--INSTRUCTION EXECUTION TIMES AND BIT PATTERNS--

This appendix summarizes the bit patterns and number of time states associated with every 8080 CPU instruction.

When using this summary, note the following symbology:

1) DDD represents a destination register. SSS represents a source register. Both DDD and SSS are interpreted as follows:

DDD or SSS	Interpretation
000	Register B
001	Register C
010	Register D
011	Register E
100	Register H
101	Register L
110	A memory register
111	The accumulator

2) Instruction execution time equals number of time periods multiplied by the duration of a time period.

   A time period may vary from 480 nanosecs to 2 μsec.

   Where two numbers of time periods are shown (eg. 5/11), it means that the smaller number of time periods will be required if a condition is not met, and the larger number of time periods will be required if the condition is met.

MNEMONIC	D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	Number of Time Periods

APPENDIX C
SOFTWARE OPERATING COMMANDS AND MESSAGES

C.1 SYSTEM MONITOR

STARTING ADDRESS - 3800

All arguments are in hexadecimal form.

A ASSIGN I/O DEVICE

A ldev,pdev

Physical device pdev is assigned to logical device ldev

B PUNCH IN BNPF FORMAT

B low address, high address

Memory from low address to high address is punched in BNPF form.

C COMPARE PROM WITH MEMORY

C address

256 bytes of memory beginning at address are compared with a PROM in the programming socket, and miscompares are printed.

D DISPLAY IN HEXADECIMAL FORMAT

D low address, high address

Memory from low address to high address is displayed in hexadecimal form.

E END

E address

Endfile mark is created and punched; 60 null characters are punched.

F FILL MEMORY

F low address, high address, data

Memory from low address to high address is filled with data.

G GO TO

G Address, bkptl, bkpt2

Program control is transferred to address. Breakpoints are set at bkptl and bkpt2.

H HEXADECIMAL ARITHMETIC

H number, number Sp

The sum and difference of the two numbers is printed in hexadecimal.

L LOAD BNPF FORMAT

L low address, high address

A BNPF format tape is read and stored in low address through high address.

M MOVE

M low address, high address, destination address

A block of memory from low address to high address is moved to location destination address.

N PUNCH NULL

N

Sixty null characters are punched.

P PROGRAM PROM

P low address, high address, PROM address

A 1602A or 1702A PROM is programmed with data from memory location low address through high address. Programming begins at PROM location PROM address MOD 256.

R READ HEXADECIMAL TAPE

R bias address

A hexadecimal format tape is read into memory at tape address plus bias address.

S SUBSTITUTE

S address Sp

Memory at address is displayed, and can be modified by typing in new data. Termination with space opens next sequential address, termination with carriage return ends command.

X EXAMINE REGISTERS OR MEMORY

X reg ident

Register is displayed, and can be modified as in the S command.

T TRANSFER PROM TO MEMORY

T address

The contents of a PROM are loaded into memory starting at address and continuing for 256 bytes.

W WRITE HEXADECIMAL

W low address, high address

Memory from low address to high address is punched in hexadecimal format.

MESSAGES

. Monitor ready to accept commands

* Error. Reenter command

C.2 TEXT EDITOR

STARTING ADDRESS - 0010

All commands are terminated with two ESCAPE or ALT MODE characters.

A	Appends text to workspace.
B	Resets buffer pointer to beginning of workspace.
nC	Moves buffer pointer n characters.
nD	Deletes n characters.
E	Punches workspace and input tape, creates end of file.
F string	Searches for string and places buffer pointer after string.
I string	Inserts string at location of buffer pointer.
nK	Deletes n lines.
nL	Moves buffer pointer n lines.
N	Writes 60 null characters
S search string $ substitute string $	Searches for search string. If found, substitutes substitute string and leaves buffer pointer at end of substitute string.
nT	Types n lines on the teletype.
nW	Punches n lines from the beginning of the workspace and deletes the lines typed.
Z	Moves the buffer pointer to the end of the workspace.
n <command string > $$	Executes command string n times. May be nested up to eight levels.

MESSAGES

*	Editor is ready to accept commands.
START PUNCH, TYPE CHARACTER	Allows tape punch to be started prior to punching operations.
"CHARACTER" ILLEGAL IN THIS CONTEXT	Error - reenter command or command string.
WORKSPACE FULL	Self-explanatory
CANNOT FIND "string"	A 'F' or 'S' command search was unsuccessful
ESCAPE/ALT MODE	Terminates or separates commands
BREAK	Terminates command execution
LINE FEED	Identifies end of line

APPENDIX D
HEXADECIMAL PROGRAM TAPE FORMAT

The hexadecimal tape format used by the INTELLEC 8 system is a modified memory image, blocked into discrete records. Each record contains record length, record type, memory address, and checksum information in addition to data. A frame by frame description is as follows:

Frame 0	Record Mark. Signals the start of a record. The ASCII character colon (":" HEX 3A) is used as the record mark.
Frames 1,2 (0-9,A-F)	Record Length. Two ASCII characters representing a hexadecimal number in the range 0 to 'FF'H (0 to 255). This is the count of actual data bytes in the record type or checksum. A record length of 0 indicates end of file.
Frames 3 to 6	Load Address. Four ASCII characters that represent the initial memory location where the data following will be loaded. The first data byte is stored in the location pointed to by the load address, succeeding data bytes are loaded into ascending addresses.
Frames 7, 8	Record Type. Two ASCII characters. Currently all records are type 0, this field is reserved for future expansion.
Frames 9 to 9+2* (Record Length) -1	Data. Each 8 bit memory word is represented by two frames containing the ASCII characters (0 to 9, A to F) to represent a hexadecimal value 0 to 'FF'H (0 to 255).

Frames 9+2*(Record Length) to 9+2*(Record Length) +1	Checksum. The checksum is the negative of the sum of all 8 bit bytes in the record since the record mark (":") evaluated modulus 256. That is, if you add together all the 8 bit bytes, ignoring all carries out of an 8-bit sum, then add the checksum, the result is zero.

Example: If memory locations 1 through 3 contain 53F8EC, the format of the hex file produced when these locations are punched is:

:0300010053F8ECC5

HEXADECIMAL-DECIMAL INTEGER CONVERSION

The table below provides for direct conversions between hexadecimal integers in the range 0–FFF and decimal integers in the range 0–4095. For conversion of larger integers, the table values may be added to the following figures:

Hexadecimal	Decimal	Hexadecimal	Decimal
01 000	4 096	20 000	131 072
02 000	8 192	30 000	196 608
03 000	12 288	40 000	262 144
04 000	16 384	50 000	327 680
05 000	20 480	60 000	393 216
06 000	24 576	70 000	458 752
07 000	28 672	80 000	524 288
08 000	32 768	90 000	589 824
09 000	36 864	A0 000	655 360
0A 000	40 960	B0 000	720 896
0B 000	45 056	C0 000	786 432
0C 000	49 152	D0 000	851 968

APPENDIX G
I/O PORT ASSIGNMENT AND SAMPLE DEVICE DRIVERS

The INTELLEC 8I I/O system assigns specific functions to certain of the I/O ports. Table G-1 gives these assignments. When reading device status or writing device commands, each bit of the 8 bit byte transmitted may have a specific meaning or function. These are given in Tables G-2, G-3, and G-4. For examples of how to use the I/O ports and commands, sample I/O driver programs which read and punch a character using the Teletype, and which read a character from the high-speed paper tape reader are given. However, these functions should normally be performed by calling the I/O subroutines as described in Section 3.3.2.

PORT	USE
INPUT PORT 0	Teletype data in
INPUT PORT 1	Teletype/PTR status in
INPUT PORT 2	PROM data in
INPUT PORT 3	PTR data in
INPUT PORT 4	CRT data in
INPUT PORT 5	CRT status in
OUTPUT PORT 0	Teletype data out
OUTPUT PORT 1	Teletype/PTR/PROM commands out
OUTPUT PORT 2	PROM address out
OUTPUT PORT 3	PROM data out
OUTPUT PORT 4	CRT data out

Table G-1. I/O Port Assignment

NOTE: Input ports 0 through 3, and output ports 0 through 3 are located on I/O board 1.
Input ports 4 and 5, and output port 4 are located on I/O board 2.

BIT NUMBER	NORMAL VALUE	USE
0	1	If = 0, teletype input is ready
1	1	Overrun error
2	0	If = 0, teletype output is ready
3	1	Framing error
4	1	Parity error
5	0	If = 1, paper tape reader has a character
6	1	If = 1, paper tape punch is ready
7	--	Unassigned

Table G-2. Input Port 1 Bit Assignments
(Bit 0 = least significant bit)

BIT NUMBER	NORMAL VALUE	USE
0	0	Teletype reader on/off
1	0	Paper tape punch on/off
2	0	Paper tape reader on/off
3	1	PROM enable/disable (disable = 1)
4	0	Data in is true/complement
5	0	Data out is true/complement
6	0	1702 PROM programmer on/off
7	0	1702a PROM programmer on/off

Table G-3. Output Port 1 Bit Assignments

BIT NUMBER	NORMAL VALUE	USE
0	1	If = 0, input is ready
1	1	Overrun error
2	0	If = 0, output is ready
3	1	Framing error
4	1	Parity error
5	--	Unassigned
6	--	Unassigned
7	--	Unassigned

Table G-4. Input Port 5 Bit Assignments

(1) READING TAPES UNDER PROGRAM CONTROL

Bit 0 of output port 1 is used as the ON/OFF control for the teletype reader, and is normally in the 0 state. To read one character from a paper tape, set this bit to 1 and immediately set it back to 0, causing the reader to advance one frame and stop on the next character.

When the character which has been read is ready for use by the program, bit 0 of input port 1 will be set to zero by the UART device (for a description of the UART, see the INTELLEC 8 Reference Manual). The character which has been read will then be available at input port 0.

The following program section will read one character from the TTY tape reader.

NOTE: The character is transmitted in its one's complement form, i.e., each bit is inverted.

```
LABEL       CODE        OPERAND     COMMENT

PTI         EQU         0           ; TTY INPUT DATA PORT
STI         EQU         1           ; TTY INPUT STATUS PORT
STO         EQU         1           ; TTY OUTPUT COMMAND PORT
;
            MVI         A,1         ; Set bit 0 of port 1=1, pulse reader on.
            OUT         STO
            MVI         A,0         ; Set bit 0 of port 1=0, pulse reader off.
            OUT         STO
; Character has been read and is being readied by UART
BACK:       IN          STI         ; Read UART status into accumulator
            ANI         01H         ; If bit 0=1, loop to BACK
            JNZ         BACK
            IN          PTI         ; Read character from input port 0
                                    ; into accumulator
            XRI         0FFH        ; Invert each bit of transmitted
                                    ; data to produce the character
; The character is now in the accumulator and ready for use
; by the program.
```

(2) PUNCHING TAPES UNDER PROGRAM CONTROL

Tapes may be punched under program control by merely outputting data to the Teletype when the tape punch has been turned on. If, however, printing operations are taking place which are not to be punched, provisions must be made to enable the operator to start and stop the tape punch.

A good procedure to use in this case is to have the program clear the accumulator, then loop until a character is input from the teletype keyboard. This allows the operator to turn off the tape punch and then cause program execution to continue by pressing any key on the teletype keyboard.

Example: The following program section will loop until a character is input from the TTY keyboard, then will punch the character contained in the B register.

```
LABEL       CODE        OPERAND     COMMENT

STI         EQU         1           ; TTY input status port
PTO         EQU         0           ; TTY output data port
PTI         EQU         0           ; TTY input data port
; Loop waiting for a character to be typed by user.
BACK:       IN          STI         ; Is character ready
            ANI         01H         ; to be input (bit 0=0)?
            JNZ         BACK        ; If not, loop to BACK
            IN          PTI         ; Read in character to clear
                                    ; the port
; Punch the character onto the tape
TO:         IN          STI         ; Check if TTY buffer is
                                    ; available
            ANI         04H
            JNZ         TO          ; Loop until available
            MOV         A,B         ; Move character from B
                                    ; register to accumulator for punching
            XRI         0FFH        ; Invert each bit of
                                    ; character
            OUT         PTI         ; Punch character
```

(3) Reading Paper Tape using the High-Speed Paper Tape Reader

Bit 2 of Output Port 1 is used as the Step control for the high-speed paper tape reader. In order to read one character from the reader, set this bit to one and immediately reset it to zero. This produces a pulse on the reader STEP control line; the reader will advance one frame, read the data in that frame, and stop.

When the character which has been read is ready for use in the program (available on Input Port 3), bit 5 of Input Port 1 will be set to zero by the reader. The character which has been read is transmitted in its one's complement form, i.e., each bit has been inverted.

The following program section will read and input one character from the high-speed paper tape reader:

```
LABEL           CODE        OPERAND         COMMENT

HSI             EQU         3               ;HSPTR INPUT DATA PORT
SHI             EQU         1               ;HSPTR INPUT STATUS PORT
SHO             EQU         1               ;HSPTR OUTPUT COMMAND PORT
;
                MVI         A,04H           ;BIT 2, PORT 1 = 1, PULSE READER ON
                OUT         SHO
                XRA         A               ;BIT 2, PORT 1 = 0, PULSE READER OFF
                OUT         SHO
;CHARACTER HAS BEEN READ AND IS TRANSMITTED TO INPUT PORT 3
;
BACK:           IN          SHI             ;READ HSPTR STATUS INTO ACC.
                ANI         20H             ;IF STATUS BIT = 1, LOOP TO BACK:.
                JNZ         BACK
                IN          HSI             ;READ CHARACTER FROM INPUT PORT 3
                                            ;TO ACCUMULATOR
                XRI         0FFH            ;;INVERT EACH BIT OF TRANSMITTED
                                            ;DATA TO PRODUCE THE CHARACTER
;THE CHARACTER IS NOW IN THE ACCUMULATOR AND IS READY FOR USE BY THE
;PROGRAM.
